This systematic review was conducted by the 2020 Dietary Guidelines Advisory Committee in collaboration with the Nutrition Evidence Systematic Review (NESR) team at the Center for Nutrition Policy and Promotion, Food and Nutrition Service, U.S. Department of Agriculture (USDA). All systematic reviews from the 2020 Advisory Committee Project are available on the NESR website: <https://nesr.usda.gov/2020-dietary-guidelines-advisory-committee-systematic-reviews>.

Conclusion statements drawn as part of this systematic review describe the state of science related to the specific question examined. Conclusion statements do not draw implications, and should not be interpreted as dietary guidance. This portfolio provides the complete documentation for this systematic review. A summary of this review is included in the 2020 Advisory Committee's Scientific Report available at www.DietaryGuidelines.gov.

The contents of this document may be used and reprinted without permission. Endorsements by NESR, the Center for Nutrition Policy and Promotion, the Food and Nutrition Service, or the USDA of derivative products developed from this work may not be stated or implied.

In accordance with Federal civil rights law and USDA civil rights regulations and policies, the USDA, its Agencies, offices, and employees, and institutions participating in or administering USDA programs are prohibited from discriminating based on race, color, national origin, religion, sex, gender identity (including gender expression), sexual orientation, disability, age, marital status, family/parental status, income derived from a public assistance program, political beliefs, or reprisal or retaliation for prior civil rights activity, in any program or activity conducted or funded by USDA (not all bases apply to all programs). Remedies and complaint filing deadlines vary by program or incident.

Persons with disabilities who require alternative means of communication for program information (e.g., Braille, large print, audiotope, American Sign Language, etc.) should contact the responsible Agency or USDA's TARGET Center at (202) 720-2600 (voice and TTY) or contact USDA through the Federal Relay Service at (800) 877-8339. Additionally, program information may be made available in languages other than English.

To file a program discrimination complaint, complete the USDA Program Discrimination Complaint Form, AD-3027, found online at [How to File a Program Discrimination Complaint](#) and at any USDA office or write a letter addressed to USDA and provide in the letter all of the information requested in the form. To request a copy of the complaint form, call (866) 632-9992. Submit your completed form or letter to USDA by: (1) mail: U.S. Department of Agriculture, Office of the Assistant Secretary for Civil Rights, 1400 Independence Avenue, SW, Washington, D.C. 20250-9410; (2) fax: (202) 690-7442; or (3) email: program.intake@usda.gov.

USDA is an equal opportunity provider, employer, and lender.

USDA and HHS implemented a process to identify topics and scientific questions to be examined by the 2020 Dietary Guidelines Advisory Committee. The Committee conducted its review of evidence in subcommittees for discussion by the full Committee during its public meetings. The role of the Committee members involved establishing all aspects of the protocol, which presented the plan for how they would examine the scientific evidence, including the inclusion and exclusion criteria; reviewing all studies that met the criteria they set; deliberating on the body of evidence for each question; and writing and grading the conclusion statements to be included in the scientific report the 2020 Committee submitted to USDA and HHS. The NESR team with assistance from Federal Liaisons and Project Leadership, supported the Committee by facilitating, executing, and documenting the work necessary to ensure the reviews were completed in accordance with NESR methodology.

ⁱ Under contract with the Food and Nutrition Service, United States Department of Agriculture.

More information about the 2020 Dietary Guidelines Advisory Committee, including the process used to identify topics and questions, can be found at www.DietaryGuidelines.gov. More information about NESR can be found at NESR.usda.gov.

The Committee and NESR staff thank USDA's Agricultural Research Service for coordinating the peer review of this systematic review, and the Federal scientist peer reviewers for their time and expertise.

INTRODUCTION

This document describes a systematic review conducted to answer the following question: What is the relationship between maternal diet during pregnancy and lactation and risk of child food allergies and atopic allergic diseases? This systematic review was conducted by the 2020 Dietary Guidelines Advisory Committee, supported by USDA's Nutrition Evidence Systematic Review (NESR).

More information about the 2020 Dietary Guidelines Advisory Committee is available at the following website: www.DietaryGuidelines.gov.

NESR specializes in conducting food- and nutrition-related systematic reviews using a rigorous, protocol-driven methodology. More information about NESR is available at the following website: NESR.usda.gov.

NESR's systematic review methodology involves developing a protocol, searching for and selecting studies, extracting data from and assessing the risk of bias of each included study, synthesizing the evidence, developing conclusion statements, grading the evidence underlying the conclusion statements, and recommending future research. A detailed description of the systematic reviews conducted for the 2020 Dietary Guidelines Advisory Committee, including information about methodology, is available on the NESR website: <https://nesr.usda.gov/2020-dietary-guidelines-advisory-committee-systematic-reviews>. In addition, starting on page 171, this document describes the final protocol as it was applied in the systematic review. A description of and rationale for modifications made to the protocol are described in the 2020 Dietary Guidelines Advisory Committee Report, Part D: Chapter 2. Food, Beverage, and Nutrient Consumption During Pregnancy and Chapter 3. Food, Beverage, and Nutrient Consumption During Lactation.

WHAT IS THE RELATIONSHIP BETWEEN MATERNAL DIET DURING PREGNANCY AND LACTATION AND RISK OF CHILD FOOD ALLERGIES AND ATOPIC ALLERGIC DISEASES?

PLAIN LANGUAGE SUMMARY

What is the question?

- The question is: What is the relationship between maternal diet during pregnancy and lactation and risk of child food allergies and atopic allergic diseases?

What is the answer to the question?

Diet during pregnancy and risk of child food allergy

- Insufficient evidence is available to determine the relationship between lower or restricted consumption of cow milk products during pregnancy only, or during both pregnancy and lactation, and risk of food allergy in the child.
- Insufficient evidence is available to determine the relationship between peanuts, eggs, or wheat consumed during pregnancy and risk of food allergy in the child.
- Limited evidence suggests no relationship between soybean consumed during pregnancy and risk of food allergy in the child.
- No evidence is available to determine the relationship between maternal dietary patterns or fish, tree nuts and seeds, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during pregnancy and risk of food allergy in the child.

Diet during lactation and risk of child food allergy

- Insufficient evidence is available to determine the relationship between lower or restricted consumption of cow milk products during both pregnancy and lactation and risk of food allergy in the child.
- No evidence is available to determine the relationship between maternal dietary patterns or cow milk products, eggs, peanuts, soybean, wheat, fish, tree nuts and seeds, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during lactation and risk of food allergy in the child.

Diet during pregnancy and risk of child atopic dermatitis/eczema

- Moderate evidence indicates that lower or restricted consumption of cow milk products during pregnancy does not reduce the risk of atopic dermatitis/eczema in the child.
- Moderate evidence indicates that lower or restricted consumption of egg during pregnancy does not reduce the risk of atopic dermatitis/eczema in the child.
- Insufficient evidence is available to determine the relationship between cow milk products and eggs restricted during both pregnancy and lactation and risk of atopic dermatitis/eczema in the child.
- Limited evidence suggests that fish consumed during pregnancy does not increase the risk of atopic dermatitis/eczema in the child.

- Limited evidence suggests that dietary patterns during pregnancy are not associated with risk of atopic dermatitis/eczema in the child.
- Insufficient evidence is available to determine the relationship between peanuts, soybean, wheat/cereal, yogurt and probiotic milk products, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits, consumed during pregnancy and risk of atopic dermatitis/eczema in the child.
- No evidence is available to determine the relationship between tree nuts and seeds consumed during pregnancy and risk of atopic dermatitis/eczema in the child.

Diet during lactation and risk of child atopic dermatitis/eczema

- Insufficient evidence is available to determine the relationship between cow milk products restricted during both pregnancy and lactation, or during lactation only, and risk of atopic dermatitis/eczema in the child.
- Insufficient evidence is available to determine the relationship between egg consumption restricted during both pregnancy and lactation and risk of atopic dermatitis/eczema in the child.
- No evidence is available to determine the relationship between maternal dietary patterns or yogurt and probiotic milk products, eggs, fish, peanuts, tree nuts and seeds, soybean, wheat/cereal, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits, consumed during lactation and risk of atopic dermatitis/eczema in the child.

Diet during pregnancy and risk of child allergic rhinitis

- Insufficient evidence is available to determine the relationship between cow milk products (fermented or non-fermented) consumed during pregnancy only, or during both pregnancy and lactation, and risk of allergic rhinitis in the child.
- Moderate evidence indicates that lower or restricted consumption of eggs during pregnancy does not reduce the risk of allergic rhinitis in the child.
- Limited evidence suggests that dietary patterns during pregnancy are not associated with risk of allergic rhinitis in the child.
- Insufficient evidence is available to determine the relationship between fish, peanuts, tree nuts, soybean, wheat, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during pregnancy and risk of allergic rhinitis in the child.
- No evidence is available to determine the relationship between seeds consumed during pregnancy and the risk of allergic rhinitis in the child.

Diet during lactation and risk of child allergic rhinitis

- Insufficient evidence is available to determine the relationship between cow milk products consumed during both pregnancy and lactation, and risk of allergic rhinitis in the child.
- No evidence is available to determine the relationship between maternal dietary patterns or cow milk products, eggs, fish, peanuts, tree nuts and seeds, soybean, wheat, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during lactation and risk of allergic rhinitis in the child.

Diet during pregnancy and risk of child asthma

- Limited evidence suggests that a lower consumption of cow milk products during pregnancy does not reduce risk of asthma in the child.
- Insufficient evidence is available to determine the relationship between cow milk products consumed during both pregnancy and lactation and risk of asthma in the child.
- Limited evidence suggests no relationship between eggs consumed during pregnancy and risk of asthma in the child.
- Limited evidence suggests no relationship between fish consumed during pregnancy and risk of asthma in the child.
- Insufficient evidence is available to determine the relationship between maternal dietary patterns or peanuts, tree nuts, soybean, and other foods such as wheat/whole grains, vegetables, fruits, beverages, and margarine consumed during pregnancy and risk of asthma in the child.
- No evidence is available to determine the relationship between seeds consumed during pregnancy and risk of asthma in the child.

Diet during lactation and risk of child asthma

- Insufficient evidence is available to determine the relationship between cow milk products consumed during both pregnancy and lactation, or during lactation only, and risk of asthma in the child.
- Insufficient evidence is available to determine the relationship between fish, and other foods, such as margarine, oil, butter and butter-spreads, meat, and meat products consumed during lactation and risk of asthma in the child.
- No evidence is available to determine the relationship between maternal dietary patterns or eggs, peanuts, wheat, tree nuts and seeds, and soybean consumed during lactation and risk of asthma in the child.

Why was this question asked?

- This important public health question was identified by the U.S. Departments of Agriculture (USDA) and Health and Human Services (HHS) to be examined by the 2020 Dietary Guidelines Advisory Committee.

How was this question answered?

- The 2020 Dietary Guidelines Advisory Committee, Pregnancy and Lactation Subcommittee conducted a systematic review to answer this question with support from the Nutrition Evidence Systematic Review (NESR) team.

What is the population of interest?

- For the intervention/exposure, generally healthy women during pregnancy and/or lactation.
- For the outcome, infants and toddlers (birth to 24 months) and children and adolescents (ages 2-18 years).

What evidence was found?

Pregnancyⁱⁱ

- This systematic review included 36 articles that presented evidence from 15 studies that included only pregnant women and four studies that included both

pregnant and lactating women.

- Studies looked at cow milk products, eggs, fish, soybean, wheat, peanuts, and tree nuts eaten during pregnancy alone, or during both pregnancy and lactation, as well as dietary patterns and foods not considered to be major allergens, such as meat, fruits, and vegetables eaten during pregnancy and/or lactation, with respect to the outcomes.
- There were a number of limitations including:
 - Outcomes measured by methods with limited reliability.
 - Only a few studies were well-designed randomized controlled trials. Studies were mostly observational and therefore, cause-effect relationships between diet during pregnancy and the child's risk of food allergy, atopic dermatitis, allergic rhinitis, and asthma, were difficult to determine.
 - Potential bias of the studies.
 - There was little racial/ethnic, socioeconomic, and age diversity in the studies.

Lactationⁱⁱ

- This systematic review included eight articles that presented evidence from four studies that included both pregnant and lactating women, and 2 studies that included only lactating women.
- Studies looked at cow milk products, eggs, fish, soybean, wheat, peanuts, tree nuts, as well as dietary patterns and foods not considered to be major allergens, such as meat, fruits, and vegetables eaten during both pregnancy and lactation, or lactation alone, with respect to the outcomes.
- There were a number of limitations including:
 - Very few studies examined the relationship between what mothers ate during lactation alone and the child's risk of food allergy, atopic dermatitis, allergic rhinitis and asthma.
 - Potential bias of the studies.
 - There was little racial/ethnic, socioeconomic, and age diversity in the studies.

How up-to-date is this systematic review?

- This review searched for studies from January 1980 to January 2020.

ⁱⁱ Studies with interventions during both pregnancy and lactation are discussed in both pregnancy and lactation sections

TECHNICAL ABSTRACT

Background

- This important public health question was identified by the U.S. Departments of Agriculture (USDA) and Health and Human Services (HHS) to be examined by the 2020 Dietary Guidelines Advisory Committee.
- The 2020 Dietary Guidelines Advisory Committee, Pregnancy and Lactation Subcommittee conducted a systematic review to answer this question with support from the Nutrition Evidence Systematic Review (NESR) team.
- The goal of this systematic review was to examine the following question: What is the relationship between maternal diet during pregnancy and lactation and risk of child food allergies and atopic allergic diseases?

Conclusion statements and grades

Food allergy

Pregnancy

- Insufficient evidence is available to determine the relationship between lower or restricted consumption of cow milk products during pregnancy only, or during both pregnancy and lactation, and risk of food allergy in the child. (Grade: Grade not assignable)
- Insufficient evidence is available to determine the relationship between peanuts, eggs, or wheat consumed during pregnancy and risk of food allergy in the child. (Grade: Grade not assignable)
- Limited evidence suggests no relationship between soybean consumed during pregnancy and risk of food allergy in the child. (Grade: Limited)
- No evidence is available to determine the relationship between maternal dietary patterns or fish, tree nuts and seeds, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during pregnancy and risk of food allergy in the child. (Grade: Grade not assignable)

Lactation

- Insufficient evidence is available to determine the relationship between lower or restricted consumption of cow milk products during both pregnancy and lactation and risk of food allergy in the child. (Grade: Grade not assignable)
- No evidence is available to determine the relationship between maternal dietary patterns or cow milk products, eggs, peanuts, soybean, wheat, fish, tree nuts and seeds, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during lactation and risk of food allergy in the child. (Grade: Grade not assignable)

Atopic dermatitis/eczema

Pregnancy

- Moderate evidence indicates that lower or restricted consumption of cow milk products during pregnancy does not reduce the risk of atopic dermatitis/eczema in the child. (Grade: Moderate)
- Moderate evidence indicates that lower or restricted consumption of egg during pregnancy does not reduce the risk of atopic dermatitis/eczema in the child. (Grade:

Moderate)

- Insufficient evidence is available to determine the relationship between cow milk products and eggs restricted during both pregnancy and lactation and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)
- Limited evidence suggests that fish consumed during pregnancy does not increase the risk of atopic dermatitis/eczema in the child. (Grade: Limited)
- Limited evidence suggests that dietary patterns during pregnancy are not associated with risk of atopic dermatitis/eczema in the child. (Grade: Limited)
- Insufficient evidence is available to determine the relationship between peanuts, soybean, wheat/cereal, yogurt and probiotic milk products, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits, consumed during pregnancy and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)
- No evidence is available to determine the relationship between tree nuts and seeds consumed during pregnancy and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)

Lactation

- Insufficient evidence is available to determine the relationship between cow milk products restricted during both pregnancy and lactation, or during lactation only, and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)
- Insufficient evidence is available to determine the relationship between egg consumption restricted during both pregnancy and lactation and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)
- No evidence is available to determine the relationship between maternal dietary patterns or yogurt and probiotic milk products, eggs, fish, peanuts, tree nuts and seeds, soybean, wheat/cereal, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits, consumed during lactation and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)

Allergic rhinitis

Pregnancy

- Insufficient evidence is available to determine the relationship between cow milk products (fermented or non-fermented) consumed during pregnancy only, or during both pregnancy and lactation, and risk of allergic rhinitis in the child. (Grade: Grade not assignable)
- Moderate evidence indicates that lower or restricted consumption of eggs during pregnancy does not reduce the risk of allergic rhinitis in the child. (Grade: Moderate)
- Limited evidence suggests that dietary patterns during pregnancy are not associated with risk of allergic rhinitis in the child. (Grade: Limited)
- Insufficient evidence is available to determine the relationship between fish, peanuts, tree nuts, soybean, wheat, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during pregnancy and risk of allergic rhinitis in the child. (Grade: Grade not assignable)
- No evidence is available to determine the relationship between seeds consumed during pregnancy and the risk of allergic rhinitis in the child. (Grade: Grade not assignable)

assignable)

Lactation

- Insufficient evidence is available to determine the relationship between cow milk products consumed during both pregnancy and lactation, and risk of allergic rhinitis in the child. (Grade: Grade not assignable)
- No evidence is available to determine the relationship between maternal dietary patterns or cow milk products, eggs, fish, peanuts, tree nuts and seeds, soybean, wheat, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during lactation and risk of allergic rhinitis in the child. (Grade: Grade not assignable)

Asthma

Pregnancy

- Limited evidence suggests that a lower consumption of cow milk products during pregnancy does not reduce risk of asthma in the child. (Grade: Limited)
- Insufficient evidence is available to determine the relationship between cow milk products consumed during both pregnancy and lactation and risk of asthma in the child. (Grade: Grade not assignable)
- Limited evidence suggests no relationship between eggs consumed during pregnancy and risk of asthma in the child. (Grade: Limited)
- Limited evidence suggests no relationship between fish consumed during pregnancy and risk of asthma in the child. (Grade: Limited)
- Insufficient evidence is available to determine the relationship between maternal dietary patterns or peanuts, tree nuts, soybean, and other foods such as wheat/whole grains, vegetables, fruits, beverages, and margarine consumed during pregnancy and risk of asthma in the child. (Grade: Grade not assignable)
- No evidence is available to determine the relationship between seeds consumed during pregnancy and risk of asthma in the child. (Grade: Grade not assignable)

Lactation

- Insufficient evidence is available to determine the relationship between cow milk products consumed during both pregnancy and lactation, or during lactation only, and risk of asthma in the child. (Grade: Grade not assignable)
- Insufficient evidence is available to determine the relationship between fish, and other foods, such as margarine, oil, butter and butter-spreads, meat, and meat products consumed during lactation and risk of asthma in the child. (Grade: Grade not assignable)
- No evidence is available to determine the relationship between maternal dietary patterns or eggs, peanuts, wheat, tree nuts and seeds, and soybean consumed during lactation and risk of asthma in the child. (Grade: Grade not assignable)

Methods

- A literature search was conducted using four databases (PubMed, Cochrane, Embase, and CINAHL) to identify articles that evaluated the intervention or exposure of maternal diet during pregnancy and lactation and the outcomes of child food allergies and atopic allergic diseases. A manual search was conducted to

identify articles that may not have been included in the electronic databases searched. Articles were screened by two NESR analysts independently for inclusion based on pre-determined criteria.

- Data extraction and risk of bias assessment were conducted for each included study, and both were checked for accuracy. The Committee qualitatively synthesized the body of evidence to inform development of a conclusion statement(s), and graded the strength of evidence using pre-established criteria for risk of bias, consistency, directness, precision, and generalizability.

Summary of the evidence

Pregnancyⁱⁱⁱ

- This systematic review included 36 articles from five randomized controlled trials (RCTs), one non-RCT (NRCT), and 13 prospective cohort studies that assessed the association between maternal diet and risk of food allergy, atopic dermatitis/eczema, allergic rhinitis, and asthma in the child occurring from birth through 18 y of age. The articles were published between 1987 and 2020 and consisted of:
 - Thirty articles from 15 studies that included only pregnant women.
 - Six articles from four studies that included both pregnant and lactating women.
- Six articles from two RCTs and two prospective cohort studies examined maternal avoidance and/or consumption of cow milk products, eggs, soybean, wheat, and peanuts during pregnancy alone, or during both pregnancy and lactation, in relation to risk of food allergy in the child from birth through 18 y of age.
- Twenty-five articles from five RCTs, one NRCT, and 10 prospective cohort studies examined maternal dietary patterns and consumption and/or avoidance of cow milk products, eggs, fish, soybean, wheat, peanuts, tree nuts, and other foods not commonly considered to be allergens during pregnancy alone, or during both pregnancy and lactation, in relation to risk of atopic dermatitis/eczema in the child from birth through age 18 y.
- Sixteen articles from four RCTs and six prospective cohort studies examined maternal dietary patterns and avoidance and/or consumption of cow milk products, eggs, fish, soybean, wheat, peanuts, tree nuts, and other foods not commonly considered to be allergens during pregnancy alone, or during both pregnancy and lactation, in relation to risk of allergic rhinitis in the child from birth through 18 y of age.
- Nineteen articles from two RCTs and eight prospective cohort studies examined maternal dietary patterns and avoidance and/or consumption of cow milk products, eggs, fish, soybean, peanuts, tree nuts, and other foods during pregnancy alone, or during both pregnancy and lactation, in relation to risk of asthma in the child from 2 through 18 y of age.
- No articles were identified that examined maternal consumption of seeds during pregnancy in relation to risk of atopic outcomes in the child from birth through 18 y of age.
- The ability to draw strong conclusions was limited by the following issues:
 - Few RCTs have been conducted and thus, data were primarily observational in nature, limiting the ability to determine causal effects of consumption or avoidance of different foods during pregnancy and risk of

- atopic dermatitis, food allergies, allergic rhinitis, and asthma in the child.
- Key confounders were not consistently controlled for in most of the studies.
- Studies had risk-of-bias issues, such as self-reported outcomes and selection bias.
- People with lower SES, adolescents, and racially and ethnically diverse populations were underrepresented in the body of evidence.

Lactationⁱⁱⁱ

- This systematic review included eight articles from four randomized controlled trials (RCTs), one non-RCT (NRCT), and one prospective cohort study that assessed the relationship between maternal diet during both pregnancy and lactation, or during lactation alone, and risk of food allergy, atopic dermatitis/eczema, allergic rhinitis, and asthma in the child occurring from birth through 18 y of age. The included articles were published between 1989 and 2013.
 - Six articles from four studies included both pregnant and lactating women.
 - Two studies included only lactating women.
- Four articles from two RCTs examined maternal avoidance of cow milk products, eggs, soybean, wheat, and peanuts during both pregnancy and lactation, in relation to risk of food allergy and allergic rhinitis in the child from birth through 18 y of age. None of these studies were conducted exclusively in lactating women.
- Seven articles from four RCTs and one NRCT examined maternal avoidance of cow milk products, eggs, soybean, wheat, and peanuts during both pregnancy and lactation, or during lactation alone, in relation to the risk of atopic dermatitis/eczema in the child from birth through 18 y of age. Of these, only one RCT was conducted exclusively in lactating women.
- Four articles from two RCTs and one prospective cohort study examined maternal avoidance and/or consumption of cow milk products, eggs, fish, soybean, peanuts, wheat, and other foods during both pregnancy and lactation, or during lactation alone, in relation to risk of asthma in the child from 2 through 18 y of age. Of these, one prospective cohort study was conducted exclusively in lactating women.
- No articles were identified that examined maternal avoidance or consumption of seeds during lactation in relation to the risk of atopic outcomes in the child from birth through 18 y of age.
- The ability to draw strong conclusions was limited by the following issues:
 - Very few studies assessed the relationship between maternal diet during lactation alone and risk of atopic dermatitis, food allergy, allergic rhinitis, and asthma.
 - Key confounders were not consistently controlled for in most of the studies.
 - Women with lower socioeconomic status (SES), adolescents, and racially and ethnically diverse populations were underrepresented in the body of evidence.

ⁱⁱⁱ Studies with interventions during both pregnancy and lactation are discussed in both pregnancy and lactation sections

FULL REVIEW

Systematic review question

What is the relationship between maternal diet during pregnancy and lactation and risk of child food allergies and atopic allergic diseases?

Conclusion statements and grades

Food allergy

Pregnancy

Insufficient evidence is available to determine the relationship between lower or restricted consumption of cow milk products during pregnancy only, or during both pregnancy and lactation, and risk of food allergy in the child. (Grade: Grade not assignable)

Insufficient evidence is available to determine the relationship between peanuts, eggs, or wheat consumed during pregnancy and risk of food allergy in the child. (Grade: Grade not assignable)

Limited evidence suggests no relationship between soybean consumed during pregnancy and risk of food allergy in the child. (Grade: Limited)

No evidence is available to determine the relationship between maternal dietary patterns or fish, tree nuts and seeds, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during pregnancy and risk of food allergy in the child. (Grade: Grade not assignable)

Lactation

Insufficient evidence is available to determine the relationship between lower or restricted consumption of cow milk products during both pregnancy and lactation and risk of food allergy in the child. (Grade: Grade not assignable)

No evidence is available to determine the relationship between maternal dietary patterns or cow milk products, eggs, peanuts, soybean, wheat, fish, tree nuts and seeds, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during lactation and risk of food allergy in the child. (Grade: Grade not assignable)

Atopic dermatitis/eczema

Pregnancy

Moderate evidence indicates that lower or restricted consumption of cow milk products during pregnancy does not reduce the risk of atopic dermatitis/eczema in the child. (Grade: Moderate)

Moderate evidence indicates that lower or restricted consumption of egg during pregnancy does not reduce the risk of atopic dermatitis/eczema in the child. (Grade: Moderate)

Insufficient evidence is available to determine the relationship between cow milk products and eggs restricted during both pregnancy and lactation and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)

Limited evidence suggests that fish consumed during pregnancy does not increase the risk of atopic dermatitis/eczema in the child. (Grade: Limited)

Limited evidence suggests that dietary patterns during pregnancy are not associated with risk of atopic dermatitis/eczema in the child. (Grade: Limited)

Insufficient evidence is available to determine the relationship between peanuts, soybean, wheat/cereal, yogurt and probiotic milk products, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits, consumed during pregnancy and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)

No evidence is available to determine the relationship between tree nuts and seeds consumed during pregnancy and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)

Lactation

Insufficient evidence is available to determine the relationship between cow milk products restricted during both pregnancy and lactation, or during lactation only, and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)

Insufficient evidence is available to determine the relationship between egg consumption restricted during both pregnancy and lactation and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)

No evidence is available to determine the relationship between maternal dietary patterns or yogurt and probiotic milk products, eggs, fish, peanuts, tree nuts and seeds, soybean, wheat/cereal, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits, consumed during lactation and risk of atopic dermatitis/eczema in the child. (Grade: Grade not assignable)

Allergic rhinitis

Pregnancy

Insufficient evidence is available to determine the relationship between cow milk products (fermented or non-fermented) consumed during pregnancy only, or during both pregnancy and lactation, and risk of allergic rhinitis in the child. (Grade: Grade not assignable)

Moderate evidence indicates that lower or restricted consumption of eggs during pregnancy does not reduce the risk of allergic rhinitis in the child. (Grade: Moderate)

Limited evidence suggests that dietary patterns during pregnancy are not associated with risk of allergic rhinitis in the child. (Grade: Limited)

Insufficient evidence is available to determine the relationship between fish, peanuts, tree nuts, soybean, wheat, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during pregnancy and risk of allergic rhinitis in the child. (Grade: Grade not assignable)

No evidence is available to determine the relationship between seeds consumed during pregnancy and the risk of allergic rhinitis in the child. (Grade: Grade not assignable)

Lactation

Insufficient evidence is available to determine the relationship between cow milk products consumed during both pregnancy and lactation, and risk of allergic rhinitis in the child. (Grade: Grade not assignable)

No evidence is available to determine the relationship between maternal dietary patterns or cow milk products, eggs, fish, peanuts, tree nuts and seeds, soybean, wheat, and foods not commonly considered to be allergens, such as meat, vegetables, and fruits consumed during lactation and risk of allergic rhinitis in the child. (Grade: Grade not assignable)

Asthma

Pregnancy

Limited evidence suggests that a lower consumption of cow milk products during pregnancy does not reduce risk of asthma in the child. (Grade: Limited)

Insufficient evidence is available to determine the relationship between cow milk products consumed during both pregnancy and lactation and risk of asthma in the child. (Grade: Grade not assignable)

Limited evidence suggests no relationship between eggs consumed during pregnancy and risk of asthma in the child. (Grade: Limited)

Limited evidence suggests no relationship between fish consumed during pregnancy and risk of asthma in the child. (Grade: Limited)

Insufficient evidence is available to determine the relationship between maternal dietary patterns or peanuts, tree nuts, soybean, and other foods such as wheat/whole grains, vegetables, fruits, beverages, and margarine consumed during pregnancy and risk of asthma in the child. (Grade: Grade not assignable)

No evidence is available to determine the relationship between seeds consumed during pregnancy and risk of asthma in the child. (Grade: Grade not assignable)

Lactation

Insufficient evidence is available to determine the relationship between cow milk products consumed during both pregnancy and lactation, or during lactation only, and risk of asthma in the child. (Grade: Grade not assignable)

Insufficient evidence is available to determine the relationship between fish, and other foods, such as margarine, oil, butter and butter-spreads, meat, and meat products consumed during lactation and risk of asthma in the child. (Grade: Grade not assignable)

No evidence is available to determine the relationship between maternal dietary patterns or eggs, peanuts, wheat, tree nuts and seeds, and soybean consumed during lactation and risk of asthma in the child. (Grade: Grade not assignable)

Summary of the evidence

Pregnancy^{iv}

- This systematic review included 36 articles from five randomized controlled trials (RCTs), one non-RCT (NRCT), and 13 prospective cohort studies that assessed the association between maternal diet and risk of food allergy, atopic dermatitis/eczema, allergic rhinitis, and asthma in the child occurring from birth through 18 years of age. The articles were published between 1987 and 2020 and consisted of:
 - Thirty articles from 15 studies that included only pregnant women.
 - Six articles from four studies that included both pregnant and lactating women.
- Six articles from two RCTs and two prospective cohort studies examined maternal avoidance and/or consumption of cow milk products, eggs, soybean, wheat, and peanuts during pregnancy alone, or during both pregnancy and lactation, in relation to risk of food allergy in the child from birth through 18 y of age.
- Twenty-five articles from five RCTs, one NRCT, and 10 prospective cohort studies examined maternal dietary patterns and consumption and/or avoidance of cow milk products, eggs, fish, soybean, wheat, peanuts, tree nuts, and other foods not commonly considered to be allergens during pregnancy alone, or during both pregnancy and lactation, in relation to risk of atopic dermatitis/eczema in the child from birth through age 18 years.
- Sixteen articles from four RCTs and six prospective cohort studies examined maternal dietary patterns and avoidance and/or consumption of cow milk products, eggs, fish, soybean, wheat, peanuts, tree nuts, and other foods not commonly considered to be allergens during pregnancy alone, or during both pregnancy and lactation, in relation to risk of allergic rhinitis in the child from birth through 18 y of age.
- Nineteen articles from two RCTs and eight prospective cohort studies examined maternal dietary patterns and avoidance and/or consumption of cow milk products, eggs, fish, soybean, peanuts, tree nuts, and other foods during pregnancy alone, or during both pregnancy and lactation, in relation to risk of asthma in the child from 2 through 18 y of age.
- No articles were identified that examined maternal consumption of seeds during pregnancy in relation to risk of atopic outcomes in the child from birth through 18 y of age.
- The ability to draw strong conclusions was limited by the following issues:
 - Few RCTs have been conducted and thus, data were primarily observational in nature, limiting the ability to determine causal effects of consumption or avoidance of different foods during pregnancy and risk of atopic dermatitis, food allergies, allergic rhinitis, and asthma in the child.
 - Key confounders were not consistently controlled for in most of the studies.
 - Studies had risk-of-bias issues, such as self-reported outcomes and selection bias.
 - People with lower SES, adolescents, and racially and ethnically diverse populations were underrepresented in the body of evidence.

Lactation^{iv}

- This systematic review included eight articles from four randomized controlled trials (RCTs), one non-RCT (NRCT), and one prospective cohort study that assessed the relationship between maternal diet during both pregnancy and lactation, or during lactation alone, and risk of food allergy, atopic dermatitis/eczema, allergic rhinitis, and asthma in the child occurring from birth through 18 years of age. The included articles were published between 1989 and 2013.
 - Six articles from four studies included both pregnant and lactating women.
 - Two studies included only lactating women.
- Four articles from two RCTs examined maternal avoidance of cow milk products, eggs, soybean, wheat, and peanuts during both pregnancy and lactation, in relation to risk of food allergy and allergic rhinitis in the child from birth through 18 y of age. None of these studies were conducted exclusively in lactating women.
- Seven articles from four RCTs and one NRCT examined maternal avoidance of cow milk products, eggs, soybean, wheat, and peanuts during both pregnancy and lactation, or during lactation alone, in relation to the risk of atopic dermatitis/eczema in the child from birth through 18 years of age. Of these, only one RCT was conducted exclusively in lactating women.
- Four articles from two RCTs and one prospective cohort study examined maternal avoidance and/or consumption of cow milk products, eggs, fish, soybean, peanuts, wheat, and other foods during both pregnancy and lactation, or during lactation alone, in relation to risk of asthma in the child from 2 through 18 y of age. Of these, one prospective cohort study was conducted exclusively in lactating women.
- No articles were identified that examined maternal avoidance or consumption of seeds during lactation in relation to the risk of atopic outcomes in the child from birth through 18 y of age.
- The ability to draw strong conclusions was limited by the following issues:
 - Very few studies assessed the relationship between maternal diet during lactation alone and risk of atopic dermatitis, food allergy, allergic rhinitis, and asthma.
 - Key confounders were not consistently controlled for in most of the studies.
 - Women with lower socioeconomic status (SES), adolescents, and racially and ethnically diverse populations were underrepresented in the body of evidence.

^{iv} Studies with interventions during both pregnancy and lactation are discussed in both pregnancy and lactation sections

Description of the evidence

This systematic review included articles that addressed the relationship between maternal diet during pregnancy and lactation and risk of child food allergies and atopic diseases. The search included articles from very high and high Human Development Index (HDI)^v countries and the search timeframe spanned from January 1980 to January 2020. The following study designs were included: RCTs, NRCTs, prospective and retrospective cohort studies, and nested case-control studies.

The outcomes considered in this review were food allergies, atopic dermatitis, allergic rhinitis, and asthma in the child (birth to 18 years). Food allergy was defined as a diagnosis based on either the gold standard of a double-blind, placebo-controlled oral food challenge or as parental report of clinical history with blood immunoglobulin E (IgE) levels ≥ 0.35 kU/L and/or skin prick test wheal ≥ 3 mm. Because of the difficulty in diagnosing asthma during infancy and toddlerhood, only those studies that assessed asthma in children who were at least 2 years or older were included in this systematic review.

In total, 38 articles were included in the body of evidence. The evidence in this review is presented based on the outcomes: 1) Food allergy; 2) Atopic dermatitis/eczema; 3) Allergic rhinitis; and 4) Asthma.

Food Allergy

Six articles assessed the relationship between maternal diet and risk of food allergy in the child, including one from a Japanese RCT,⁸ three from a U.S.-based RCT,³⁴⁻³⁶ and one each from two prospective cohort studies.^{4,12} A total of four distinct groups of trials/cohort studies were represented in this body of evidence. References are included for each study in **Table 1** with trial/cohort names or locations when names were unavailable.

One RCT³⁴⁻³⁶ and one prospective cohort study⁴ were conducted in the U.S. One study each was conducted in Japan⁸ and the U.K.¹²

Participant characteristics

- Sample size of the studies ranged from 350⁸ to 13,971.¹²
- Among the studies that reported these characteristics, all included participants were adult women with singleton pregnancies.
- Health characteristics:
 - RCTs recruited participants who exclusively³⁴⁻³⁶ or predominantly⁸ had a personal and/or family history of allergies.
 - In the prospective cohort studies,^{4,12} participants represented the general

^v The Human Development classification was based on the Human Development Index (HDI) ranking from the year the study intervention occurred or data were collected (UN Development Program. HDI 1990-2017 HDRO calculations based on data from UNDESA (2017a), UNESCO Institute for Statistics (2018), United Nations Statistics Division (2018b), World Bank (2018b), Barro and Lee (2016) and IMF (2018). Available from: <http://hdr.undp.org/en/data>). If the study did not report the year in which the intervention occurred or data were collected, the HDI classification for the year of publication was applied. HDI values are available from 1980, and then from 1990 to present. If a study was conducted prior to 1990, the HDI classification from 1990 was applied. When a country was not included in the HDI ranking, the current country classification from the World Bank was used instead (The World Bank. World Bank country and lending groups. Available from: <https://datahelpdesk.worldbank.org/knowledgebase/articles/906519-world-country-and-lending-groups>).

population and the majority were not from families with high risk of allergies.

- Race/ethnicity:
 - The U.S.-based RCT³⁴⁻³⁶ and Project Viva cohort study⁴ noted that the participants were predominantly White (defined as ≥ 50 percent of the participants). One RCT included participants that were 100 percent from Japan.⁸
 - One prospective cohort study did not report race/ethnicity of participants.¹²
- Socio-economic status:
 - Maternal education:
 - One U.S.-based RCT³⁴⁻³⁶ and prospective cohort study⁴ reported that the majority of participants had some higher education.
 - One RCT⁸ and one cohort study¹² did not report on maternal education.
 - Income/Employment Status:
 - The majority of women were employed and/or from middle-to-high income households in a U.S.-based trial³⁴⁻³⁶ and Project Viva cohort study⁴ that reported household income and/or participant employment status.
 - One RCT⁸ and one cohort study¹² did not report on income or employment status.

Atopic dermatitis/eczema

Twenty six articles, including eight from six RCTs,^{7,8,14,16,34-37} one NRCT,¹⁰ and 17 from 10 prospective cohort studies^{1,3-5,11,13,15,16,21-29,31} assessed the association between maternal diet and risk of atopic dermatitis. A total of 18 distinct groups of trials/cohort studies were represented in this body of evidence. References are included for each study in **Table 1** with trial/cohort names or locations when names were unavailable.

One RCT⁸ and two prospective cohort studies were conducted in Japan.^{21-26,28} In addition, three studies were conducted in the U.K.,^{1,16,29,31} and two studies each in Sweden^{7,14} and the U.S.,^{4,34-36} and one each in the Netherlands,^{13,27} Norway,³ Germany,¹⁰ Singapore,¹⁵ Thailand,³⁷ Spain/Greece,⁵ and Poland/U.S.¹¹

Participant characteristics

- Sample size of the studies ranged from 44¹⁶ to 40,641.³
- From the studies that reported these characteristics, almost all included participants who were adult women with singleton pregnancies.
 - Bédard et al¹ reported ~2.5 percent twin pregnancies in the ALSPAC cohort, Falth-Magnusson et al⁷ and Lovegrove et al¹⁶ each included one pair of twins in the trial, and Lilja et al¹⁴ included four pairs of twins.
- Health characteristics:
 - The NRCT¹⁰ and all the RCTs recruited participants who exclusively^{7,14,16,34-37} or predominantly⁸ had a personal and/or family history of allergies.

- In the prospective cohort studies,^{1,3-5,11,13,15,16,21-29,31} participants represented the general population and the majority were not from families with high risk of allergies.
- Race/ethnicity:
 - The U.S.-based RCT³⁴⁻³⁶ and Project Viva cohort,⁴ as well as the U.K.-based ALSPAC cohort,^{1,29} noted that the participants were predominantly White (defined as ≥50 percent of the participants). The Growing Up in Singapore Towards Healthy Outcomes (GUSTO) cohort based in Singapore reported that all of its participants were of Asian race.¹⁵ One RCT⁸ and two prospective cohort studies^{21-26,28} included participants that were 100 percent from Japan, while one article from the Generation R cohort specified that participants were Dutch women.¹³
 - Four RCTs,^{7,14,16,37} the NRCT,¹⁰ and four cohort articles did not report race/ethnicity of the mothers.^{3,5,11,27,31}
- Socio-economic status:
 - Maternal education:
 - One U.S.-based RCT,³⁴⁻³⁶ the NRCT,¹⁰ and seven prospective cohort studies^{1,4,11,13,15,21-27,29} reported that the majority of participants had some higher education. The study based in Greece and Spain reported that ~34 percent of participants had a high educational level,⁵ while participants in one U.K.-based cohort were a median age of 18.5 years when they left full-time education.³¹
 - Five RCTs^{7,8,14,16,37} did not report maternal education.
 - Income/Employment Status:
 - The majority of women were employed and/or from middle-to-high income households in one U.S.-based RCT³⁴⁻³⁶ and four prospective cohort studies.^{4,13,21-28,31}
 - About 17 percent of participants in one ALSPAC cohort article¹ responded yes to experiencing financial difficulties, while ~26 percent of participants in a second ALSPAC cohort article reported many financial difficulties.²⁹
 - Five RCTs,^{7,8,14,16,37} the NRCT,¹⁰ and four cohorts^{3,5,11,15} did not report income or employment status.

Allergic rhinitis

Sixteen articles, including six from four RCTs^{7,8,14,34-36} and 10 from six prospective cohort studies,^{1,3,4,15,17-20,29,31} assessed the association between maternal diet and risk of allergic rhinitis in the child. A total of 10 distinct groups of trials/cohort studies were represented in this body of evidence. References are included for each study in **Table 1** with trial/cohort names or locations when names were unavailable. One RCT³⁴⁻³⁶ and one prospective cohort study⁴ were conducted in the U.S., while one prospective cohort study was conducted in Denmark.¹⁷⁻²⁰ Two studies were conducted in Sweden,^{7,14} while two cohort studies were conducted in the U.K.^{1,29,31} One study each was conducted in Singapore,¹⁵ Norway,³ and Japan.⁸

Participant characteristics

- Sample size of the studies ranged from 171¹⁴ to 61,909.¹⁸

- From the studies that reported these characteristics, almost all included participants who were adult women with singleton pregnancies.
 - ~1 percent of participants were younger than 20 years in the Danish National Birth Cohort.¹⁷⁻²⁰
 - Bédard et al¹ reported ~2.5 percent twin pregnancies in the ALSPAC cohort, Falth-Magnusson et al⁷ included one pair of twins in the trial, and Lilja et al¹⁴ included four pairs of twins.
- Health characteristics:
 - RCTs recruited participants who exclusively^{7,14,34-36} or predominantly⁸ had a personal and/or family history of allergies.
 - In the prospective cohort studies,^{1,3,4,15,17-20,29,31} participants represented the general population and the majority were not from families with high risk of allergies.
- Race/ethnicity:
 - The U.S.-based RCT³⁴⁻³⁶ and Project Viva cohort study,⁴ as well as the U.K.-based ALSPAC cohort,^{1,29} noted that the participants were predominantly White (defined as ≥50 percent of the participants). The GUSTO cohort based in Singapore reported that all of its participants were of Asian race.¹⁵ One RCT included participants that were 100 percent from Japan.⁸
 - Two RCTs^{7,14} and three prospective cohort studies^{3,17-20,31} did not report race/ethnicity of participants.
- Socio-economic status:
 - Maternal education:
 - One U.S.-based RCT³⁴⁻³⁶ and four prospective cohort studies^{1,3,4,15,29} reported that the majority of participants had some higher education. Participants in one U.K.-based cohort were a median age of 18.5 years when they left full-time education.³¹
 - Three RCTs^{7,8,14} and one Danish cohort did not report on maternal education.¹⁷⁻²⁰
 - Income/Employment Status:
 - The majority of women were employed and/or from middle-to-high income households in one U.S.-based RCT³⁴⁻³⁶ and the Project Viva cohort,⁴ one U.K.-based cohort,³¹ and the Danish National Birth Cohort.¹⁷⁻²⁰
 - About 17 percent of participants in one ALSPAC cohort report¹ responded yes to experiencing financial difficulties, while ~26 percent of participants in a second ALSPAC cohort report indicated many financial difficulties.²⁹
 - Three RCTs^{7,8,14} and two cohorts^{3,15} did not report on income or employment status.

Asthma

Twenty articles, including three from two RCTs^{8,34,36} and 17 from nine prospective cohort studies,^{1-4,6,9,17-20,27,29-33,38} assessed the association between maternal diet and risk of asthma in the child. A total of 11 distinct groups of trials/cohort studies were represented in this body of evidence. References are included for each study in **Table 1** with trial/cohort names or locations when names were unavailable.

One RCT^{34,36} and one prospective cohort study^{4,9,33} were conducted in the U.S. One prospective cohort study was conducted in Denmark,¹⁷⁻²⁰ while two cohort studies were conducted in the U.K.^{1,2,29,31} One cohort study was conducted in Ireland,^{6,30} while two cohort studies were conducted in the Netherlands.^{27,32} One study each was conducted in Norway,³ Finland,³⁸ and Japan.⁸

Participant characteristics:

- Sample size of the studies ranged from 350⁸ to 61,909.¹⁸
- Among the studies that reported these characteristics, majority of included participants were adult women with singleton pregnancies.
 - About 1 percent of participants were younger than 20 years in the Danish National Birth Cohort,¹⁷⁻²⁰ while ~2 percent of participants were younger than 18 years in an Irish cohort.^{6,30}
 - Bédard et al^{1,2} reported ~2.5 percent twin pregnancies in the ALSPAC cohort.
- Health characteristics:
 - RCTs recruited participants who exclusively^{34,36} or predominantly⁸ had a personal and/or family history of allergies.
 - In the prospective cohort studies,^{1-4,6,9,17-20,27,29-33,38} participants represented the general population and the majority were not from families with high risk of allergies.
- Race/ethnicity:
 - The U.S.-based RCT^{34,36} and Project Viva cohort study,^{4,9,33} as well as the U.K.-based ALSPAC cohort,^{1,2,29} noted that the participants were predominantly White (defined as ≥ 50 percent of the participants). Participants in the Lifeways Cross-Generation cohort study were 100 percent Irish-born.^{6,30} One RCT included participants that were 100 percent from Japan.⁸
 - Seven prospective cohort studies did not report race/ethnicity of participants.^{3,17-20,27,31,32,38}
- Socio-economic status:
 - Maternal education:
 - One U.S.-based RCT^{34,36} and six prospective cohort studies^{1-4,6,9,27,29,30,33} reported that the majority of participants had some higher education. Participants in one U.K.-based cohort were a median age of 18.5 years, when they left full-time education,³¹ while a cohort based in the Netherlands reported that ~34 percent of participants had a high educational level at baseline.³²
 - One RCT⁸ and two cohort studies did not report maternal education level.^{17-20,38}
 - Income/Employment Status:
 - The majority of women were employed and/or from middle-to-high income households in one U.S.-based RCT^{34,36} and the Project Viva cohort,^{4,9,33} one U.K.-based cohort,³¹ the Generation R cohort,²⁷ and the Danish National Birth Cohort.¹⁷⁻²⁰
 - About 17 percent of participants in two ALSPAC cohort responded yes to experiencing financial difficulties,^{1,2} while ~26 percent of participants in a third ALSPAC cohort indicated many financial

difficulties.²⁹ About 16 percent of participants were eligible for free healthcare in the Lifeways Cross-Generation cohort study.^{6,30}

- One RCT⁸ and three cohorts^{3,32,38} did not report on income or employment status.

Interventions/Exposures

The intervention/exposure for this review was intentionally broad and included foods or food groups that may or may not be considered allergens. This review, however, did not assess the relationship between specific nutrients or dietary supplements and allergies and atopic allergic diseases. Studies included in this body of evidence assessed maternal diet during pregnancy and/or lactation in three main ways:

Avoidance diet

Six RCTs^{7,8,14,16,34-37} and one NRCT¹⁰ focused on maternal avoidance of specific foods/food groups including:

- Cow milk products^{8,16,37}
- Cow milk products and egg^{7,10,14}
- Cow milk products, egg, peanut, soy, and wheat³⁴⁻³⁶

Dietary patterns

Dietary patterns (DP) were assessed using an 1) index/score analysis or a 2) factor analysis and principal component analysis. A description of the studies categorized by the method used to measure dietary patterns is included below:

- Five articles representing four cohorts used the following indices/scores summarized below:
 - Mediterranean DP⁵
 - Diet quality score²⁷
 - Mediterranean diet score¹
 - Dietary Inflammatory Index (DII)⁹
 - Healthy Eating Index (HEI)⁶
- Three articles assessed dietary patterns using factor analysis or principal component analysis:
 - Healthy DP, Western DP, and Japanese DP²¹
 - Vegetable, fruit and white rice DP, Seafood and noodles DP, Pasta, cheese and processed meat DP¹⁵
 - Health conscious DP, Traditional DP, Processed DP, Vegetarian DP and Confectionary DP²⁹

Food/beverage consumption levels

Twenty-two articles from 13 cohort studies compared the association between different consumption levels of a variety of different foods and beverages and risk of atopic outcomes, including:

- Dairy products^{4,5,18,22,26,28,32,38}
 - Yogurt and fermented milk products^{3,18,22,26,28,32}
- Peanuts^{4,17}
- Nuts^{5,17,32}
- Wheat/cereals^{4,5,31}
- Fish^{5,11,13,19,24,25,28,30-32,38}
- Eggs^{4,32}
- Soybean^{4,12}
- Foods not commonly considered to be allergens (as reported by the studies)
 - Fruits^{2,5,23,31,32}
 - Vegetables^{2,5,23,30-32}
 - Sugar-sweetened beverages^{20,33}
 - Artificially-sweetened soft drinks²⁰
 - Margarine/oil/fats^{31,38}
 - Meat^{5,24,25,28,38}

Time point of intervention/exposure

The RCTs and NRCT began the avoidance diets at different time points:

- Early third trimester through the end of pregnancy^{7,14} or through early

lactation³⁴⁻³⁶

- Late third trimester through early lactation^{8,10,16}
- After delivery through early lactation³⁷

Most of the cohort studies administered a food frequency questionnaire (FFQ) or 24h recall at a single time point during pregnancy.^{1-3,5,6,11-13,15,17-32} In the Project Viva cohort, dietary data were collected at multiple time points during pregnancy and assessed at individual time points (e.g. by trimester) or combined in the analysis.^{4,9,33} In one cohort study, maternal dietary data were collected at a single time point during lactation by a FFQ.³⁸

Outcome

Food allergy was defined as a diagnosis based on either the gold standard of a double-blind, placebo-controlled oral food challenge,¹² or as parental report of clinical history together with blood IgE levels ≥ 0.35 kU/L and/or skin prick test wheal ≥ 3 mm.^{4,8,12,34-36} Studies that reported food sensitization only, based solely on IgE levels or a skin prick test, were excluded.

Atopic dermatitis/eczema, allergic rhinitis, and asthma outcomes in this body of evidence were measured in three ways:

- Self-reported symptoms, prescription, or doctor diagnosis via a questionnaire^{1-5,8,9,13,15,17-29,31-33,38}
- Clinical examination^{6,7,10,14,16,30,34-37}
- Hospital admission and prescription registries¹⁷⁻²⁰

Because of the difficulty in diagnosing asthma during infancy and toddlerhood, only those studies that assessed asthma in children who were at least 2 years or older were included in this systematic review.

Evidence synthesis – Food allergy

With six articles,^{4,8,12,34-36} there is a smaller body of evidence available to examine the relationship between maternal diet during pregnancy and lactation and food allergies in the child.

Cow milk products

Pregnancy: A U.S.-based cohort study⁴ showed no association between maternal consumption of milk during pregnancy in the first and second trimesters and risk of food allergy in the child.

Pregnancy and lactation: A Japan-based RCT,⁸ conducted in high-risk families, randomized mothers to consume hypoallergenic formula and avoid cow milk products during late pregnancy and lactation. Results showed no difference in the prevalence of overall allergies between children of the intervention and control group mothers and median blood IgE levels of infants did not differ between groups at 4 months of age.

Three additional articles from one U.S.-based trial³⁴⁻³⁶ assessed the effect of a prophylactic treatment, which included avoidance of cow milk, egg, and peanut during the third trimester and while lactating, on development of atopy in children from high-risk families. In addition to the intervention in the mothers, infants in the intervention group also received an intervention, which included the following: a) casein

hydrolysate formula when supplementing human milk and during weaning, b) not started on solid food until 6 months of age, c) cow milk, corn, soy, citrus and wheat restriction until 12 months of age, and d) eggs, peanut, and fish restriction until 24 months of age. The mothers in the control group followed a standard diet during pregnancy and lactation their infants were supplemented with standard infant formula (Enfamil) during human milk feeding and weaning; solid foods were introduced to control group infants in accordance with standard guidance by the American Academy of Pediatrics. While the three articles from this RCT³⁴⁻³⁶ met the inclusion criteria and findings are reported in **Table 2**, they were not considered in evidence synthesis, grading, or when drawing conclusions because of confounding from the additional child intervention. The trial also had limitations regarding risk of bias due to randomization, attrition rate (38 percent in intervention vs. 13 percent in control group; $p < 0.001$), and non-blinding of the outcome assessors and participants.

Lactation: No studies assessed the relationship between maternal consumption of cow milk products during lactation and risk of food allergy in the child.

Egg

Pregnancy: A U.S.-based cohort study⁴ showed no association between maternal consumption of eggs during the first and second trimesters and risk of food allergy in the child.

Pregnancy and lactation: As described above (p. 31), three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions.

Lactation: No studies assessed the relationship between maternal consumption of eggs during lactation and risk of food allergy in the child.

Peanut, tree nut and seed

Pregnancy: One prospective cohort study⁴ conducted in the U.S. showed no association between maternal peanut consumption during the first and second trimesters and risk of food allergy in the child.

No study assessed the relationship between maternal tree nut and seed consumption during pregnancy and risk of food allergy in the child.

Pregnancy and lactation: Three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: No study assessed the relationship between maternal peanut, tree nut and seed consumption during lactation and risk of food allergy in the child.

Soy

Pregnancy: Two prospective cohort studies, one based in the U.S.⁴ and another based in the U.K.,¹² showed no association between maternal soy consumption during pregnancy and risk of food allergy in the child. Note: The U.K. study assessed the association between maternal soybean meat consumption (data collected prospectively) during pregnancy and risk of peanut allergies diagnosed using a food challenge in the child. While the study also assessed the association between maternal peanut consumption and risk of peanut allergies in the child, this data was collected retrospectively and did not meet the inclusion-exclusion criteria.

Pregnancy and lactation: Three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: There were no studies that assessed the relationship between maternal soy consumption during lactation and risk of food allergy in the child.

Wheat

Pregnancy: A U.S.-based cohort study⁴ showed no association between maternal wheat consumption during pregnancy in the first and second trimesters and risk of food allergy in the child.

Pregnancy and lactation: Three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: No studies assessed the relationship between maternal wheat consumption during lactation and risk of food allergy in the child.

Other foods

Pregnancy: No study assessed the relationship between maternal consumption of other foods not commonly considered to be allergens, during lactation and risk of food allergy in the child.

Assessment of the evidence^{vi}

Soy

The following conclusion statement was supported by two cohort studies^{4,12} and was graded “limited.” The individual grading elements are discussed below.

“Limited evidence suggests no relationship between soybean consumed during pregnancy and risk of food allergy in the child.”

As outlined and described below, the body of evidence examining soybean consumed during pregnancy and risk of food allergy in the child was assessed for the following elements used when grading the strength of evidence.

- **Risk of bias (Table 8)** was graded as limited as there were serious flaws in the design and conduct of the studies, which are described below:
 - At least one of the key confounders was not controlled for in the U.S.-based cohort study⁴ and none of the key confounders were accounted for in the U.K.-based study.¹²
 - Dietary data reflected dietary intake at a single time point during pregnancy and may not have reflected the intake during the entire period of pregnancy. In the U.K. study, the exposure status (i.e., soybean meat) and methods used to assess exposure were not clearly defined. Further, the U.K. study did not assess the impact of consumption of a particular food with regard to the development of

^{vi} A detailed description of the methodology used for grading the strength of the evidence is available on the NESR website: <https://nesr.usda.gov/2020-dietary-guidelines-advisory-committee-systematic-reviews> and in Part C of the following reference: Dietary Guidelines Advisory Committee. 2020. *Scientific Report of the 2020 Dietary Guidelines Advisory Committee: Advisory Report to the Secretary of Agriculture and the Secretary of Health and Human Services*. U.S. Department of Agriculture, Agricultural Research Service, Washington, DC.

allergies to that particular food.

- One study assessed outcomes using non-validated or unreliable measures (e.g., parent report of a child's symptoms or parent's report of a physician diagnosis).
- None of the included studies had a pre-registered data analysis plan. Further, there was a likelihood of selective reporting in the U.K. study.
- **Consistency** was graded as strong since both studies consistently reported no association between soy consumption during pregnancy and risk of food allergy in the child.
- **Directness** was graded as limited. Although the U.K. study reported the association between maternal soybean meat consumption during pregnancy and risk of food allergy in the child, it was not the primary purpose of the study. While the U.S.-based study focused on addressing the systematic review question, these data were from a large cohort study (Project Viva) that addressed associations between different exposures and outcomes.
- **Precision** was graded as limited. Even though both studies had a moderate to large number of participants (11,352 participants¹² and approximately 600 participants⁴), there were only two cohort studies included in this body of evidence. However, neither of them unduly affected the findings of this systematic review.
- **Generalizability** was graded as limited. Although one of the studies was conducted in the U.S., the participants were predominantly White and were from mid-to-high SES. In the U.K.-based study, the authors provided minimal information on the race/ethnicity or other demographic characteristics.

Other foods

The bodies of evidence that assessed the relationship between:

- Lower or restricted consumption of cow milk products during pregnancy, or during pregnancy and lactation,
- Peanuts, eggs, or wheat consumed during pregnancy,

and risk of food allergy in the child were rated 'grade not assignable' for one or more of the following reasons:

- a very small body of evidence, usually less than two studies,
- heterogeneity in the findings,
- serious flaws in the design and conduct of the study, and
- limited generalizability of the findings to the U.S. population.

Evidence synthesis – Atopic dermatitis/eczema

With 26 articles,^{1,3-5,7,8,10,11,13-16,21-29,31,34-37} there is a substantial body of evidence available to examine the relationship between maternal diet during pregnancy and/or lactation and atopic dermatitis/eczema in the child (**Table 3**).

Cow milk products

Pregnancy: Seven studies, including two RCTs^{7,14} and five prospective

cohorts,^{4,5,22,26,28} assessed the relationship between cow milk products consumed during pregnancy and risk of atopic dermatitis/eczema. The RCTs were specifically designed to assess the relationship between the avoidance of cow milk products during pregnancy and atopic dermatitis/eczema in the child, whereas the cohort studies assessed the association between consumption of cow milk products and atopic dermatitis/eczema. As mentioned elsewhere, the RCTs primarily recruited high-risk families and this was not the case with prospective cohort studies.

None of the studies showed an association between maternal cow milk product consumption and atopic dermatitis/eczema. The only exception was a sub-group analysis in a Project Viva cohort study⁴ that showed that maternal milk consumption during the first trimester was associated with a lower risk of atopic dermatitis only among children whose parents had atopy. However, there was no association between second trimester cow milk consumption and atopic dermatitis risk in child, irrespective of parental atopy.

Pregnancy and lactation: The three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria. The findings are presented in Table 3. However, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: One Thailand-based RCT³⁷ with 62 participants showed that infants born to the mothers who were randomized to a dairy product-restricted diet (vs. usual diet) had lower incidence of atopic dermatitis at 4 months of age.

Fermented milk and yogurt

Pregnancy: Two of the three cohort studies^{3,26} showed an association between higher fermented milk and yogurt consumed during pregnancy and risk of atopic dermatitis/eczema. Specifically, in a Japanese study with a sample size of 1,354 participants, Miyake et al (2014)²⁶ noted that higher maternal yogurt intake during pregnancy was associated with a lower odds of physician-diagnosed atopic eczema in children aged 23 to 29 months. In a Norwegian cohort with 40,614 participants, Bertelsen et al³ showed that higher maternal probiotic milk and yogurt consumption (vs. no consumption) was associated with a reduced risk of atopic eczema in the infant at 6 months of age. There was no association with eczema in the child at 18 months of age. In a stratified analysis, the authors compared no intake vs. child intake only vs. mother intake only vs. mother and child intake only and risk of eczema at 18 months and noted the following:

- Maternal intake only (vs. no intake) was associated with an increased risk of atopic eczema at 18 months in children (RR: 1.08, 95% CI: 1.01, 1.15)
- Mother and child intake (vs. no intake) was associated with statistically significant lower eczema risk at 18 months (RR: 0.93, 95% CI: 0.86, 1.00)

An earlier study published by Miyake et al²² in 2010 showed that yogurt consumption during pregnancy was not associated with the risk of atopic dermatitis in the child. While the findings of this cohort study were not statistically significant, the directionality was consistent with the overall findings of the other two studies.^{26 3.}

None of the studies assessed an association between maternal fermented milk and yogurt consumption during lactation and risk of atopic dermatitis/eczema.

Egg

Pregnancy: Four studies, including two RCTs^{7,14} and two cohort studies,^{4,28} assessed the relationship between maternal egg consumption/avoidance during pregnancy and risk of atopic dermatitis. Specifically, the two trials^{7,14} conducted in Sweden that randomized mothers to avoid egg consumption during pregnancy (in addition to avoiding milk products) showed no relationship between the avoidance diet and the risk of atopic dermatitis/eczema in the child. These findings were in line with the results of the U.S.-based cohort study⁴ and a Japanese cohort study,²⁸ which both showed no association between eggs consumed during pregnancy and risk of atopic dermatitis in the child at 3-4 months of age²⁸ or 7.9 years.⁴

Pregnancy and lactation: A German NRCT (baseline n=150) showed that maternal avoidance of egg (in addition to avoiding cow milk products) during pregnancy and lactation was not associated with the risk of atopic dermatitis in the child during the first year of life (6 months, or 12 months).¹⁰

The three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: There were no other studies that assessed the relationship between maternal egg consumption during lactation and risk of atopic dermatitis/eczema in the child.

Fish

Pregnancy: Two of the seven cohort articles showed that higher consumption of fish during pregnancy was associated with a lower risk of atopic dermatitis/eczema in the child. Specifically, a U.K.-based cohort study³¹ with a baseline sample size of 1,751 participants showed that higher maternal total fish consumption during pregnancy was associated with a lower risk of doctor-confirmed eczema in 5 year old children. Similarly, a cohort study¹¹ conducted in the Poland and the U.S. showed that higher maternal fish intake was associated with a lower risk of atopic dermatitis/eczema during the first year of life. Five other articles (from 4 cohorts) showed no association with the risk of atopic dermatitis during the first 2 years of life.^{5,13,24,25,28} Three of these were conducted in Japan and two were conducted in a European population and all had at least 1,000 participants at baseline.

Lactation: No studies assessed the relationship between maternal fish consumption during lactation and risk of atopic dermatitis/eczema in the child.

Peanut, tree nut and seed

Pregnancy: Two studies, a U.S.-based cohort⁴ (baseline n=2,128) and a study based in Spain and Greece⁵ (baseline n=2,984), assessed the association between maternal peanut/nut consumption during pregnancy and risk of atopic dermatitis/eczema in the child and neither study showed an association. Of note, the Spain/Greece-based cohort study assessed nut consumption along with fruit consumption.

No studies showed an association between maternal tree nut and seed consumption during pregnancy and risk of atopic dermatitis/eczema in the child.

Pregnancy and lactation: Three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: None of the studies assessed the relationship between maternal peanuts,

tree nuts, or seed consumption during lactation and risk of atopic dermatitis/eczema in the child.

Soy

Pregnancy: The only prospective cohort study⁴ that assessed the relationship between maternal soybean consumption during pregnancy and risk of atopic dermatitis/eczema in the child showed no association.

Pregnancy and lactation: The three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: No other studies assessed the relationship between maternal soybean consumption during lactation and risk of atopic dermatitis/eczema in the child.

Wheat

Pregnancy: One U.S.-based cohort study⁴ showed that maternal wheat consumption during the second trimester was associated with a lower risk of atopic dermatitis in the child at 7.9 years. However, there was no association between first trimester maternal wheat consumption and risk of atopic dermatitis/eczema in the child. A European cohort study⁵ conducted in Spain and Greece showed no association between maternal cereal consumption and risk of atopic dermatitis/eczema in the first year of life.

Pregnancy and lactation: Three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: None of the studies assessed the relationship between maternal wheat consumption during lactation and risk of atopic dermatitis/eczema in the child.

Dietary patterns

Pregnancy: Six articles from five studies^{1,5,15,21,27,29} assessed the association between maternal DPs during pregnancy and risk of atopic dermatitis/eczema in the child. As described below, the studies assessed a variety of DPs:

1. Healthy DP, Western DP, and Japanese DP²¹
2. Mediterranean DP⁵
3. Diet quality score²⁷
4. Vegetable, fruit and white rice DP, Seafood and noodles DP, Pasta, cheese and processed meat DP¹⁵
5. Mediterranean diet score¹
6. Health conscious DP, Traditional DP, Processed DP, Vegetarian DP and Confectionary DP²⁹

Despite the heterogeneity in the DPs, none of the maternal DPs during pregnancy were associated with the risk of atopic dermatitis/eczema in the child.

Lactation: There were no studies that assessed the relationship between maternal DPs consumed during lactation and atopic dermatitis/eczema in the child.

Other foods

Pregnancy: Five articles from three cohort studies assessed the relationship between

maternal consumption of other foods not commonly considered to be allergens, such as meat,^{5,24,25,28} vegetables,^{5,23} and fruits^{5,23} during pregnancy and atopic dermatitis/eczema risk and noted the following:

- *Meat*: A Japanese cohort²⁸ with a baseline sample size of 1,002 participants showed that higher consumption of meat was associated with an increased risk of atopic dermatitis/eczema in the child; however, three other studies^{5,24,25} (including one study from the same Japanese cohort²⁴) showed no association.
- *Vegetables*: Of the two cohorts that assessed the association between maternal vegetable consumption and atopic dermatitis/eczema, the Japanese cohort²³ (baseline n=1,002) showed that a greater adherence to green and yellow vegetables was associated with a lower risk of atopic dermatitis/eczema in children at 16-24 months. However, intake of total vegetables and other vegetables was not associated with the risk of atopic dermatitis/eczema. Similarly, there were no associations between maternal vegetable consumption during pregnancy and atopic dermatitis/eczema risk in children at approximately 9-14 months in a European cohort.⁵
- *Fruits*: The same cohorts described in the above vegetables section also assessed the relationship between maternal fruit consumption during pregnancy and atopic dermatitis/eczema risk in the child.^{5,23} While the Japanese cohort²³ showed that higher citrus fruit consumption was associated with a lower atopic dermatitis/eczema risk, no association was observed with maternal total fruit and apple consumption. Similarly, a European cohort study during pregnancy⁵ found no association between fruit consumption (which was jointly assessed with nut consumption) and the risk of atopic dermatitis/eczema in the child.

Assessment of the evidence^{vii}

Cow milk products

The following conclusion statement was supported by two RCTs^{7,14} and five cohort studies^{4,5,22,26,28} and was graded “moderate.” Below, the individual grading elements are discussed separately for every study design.

“Moderate evidence indicates that lower or restricted consumption of cow milk products during pregnancy does not reduce the risk of atopic dermatitis/eczema in the child.”

As outlined and described below, the body of evidence examining consumption of cow milk products during pregnancy and risk of atopic dermatitis/eczema in the child was assessed for the following elements used when grading the strength of evidence.

- **Risk of bias** was graded as moderate for the RCTs and limited for the cohort studies.
 - **RCTs (Table 6)**: The two RCTs included in this body of evidence had notable flaws, as described below:

^{vii} A detailed description of the methodology used for grading the strength of the evidence is available on the NESR website: <https://nesr.usda.gov/2020-dietary-guidelines-advisory-committee-systematic-reviews> and in Part C of the following reference: Dietary Guidelines Advisory Committee. 2020. *Scientific Report of the 2020 Dietary Guidelines Advisory Committee: Advisory Report to the Secretary of Agriculture and the Secretary of Health and Human Services*. U.S. Department of Agriculture, Agricultural Research Service, Washington, DC.

- Falth-Magnusson et al⁷ reported issues with adherence to the assigned intervention. There was differential adherence to the intervention: 79 of the 104 mothers randomized to the intervention group adhered to the cow milk- and egg-free diet and provided follow-up data on their children at 18 months, while 102 of the 108 women randomized to control group adhered to the standard diet and provided follow-up data on their children at 18 months.
 - Lilja et al¹⁴ reported potential issues with randomization. Mothers in the intervention group reported significantly higher IgE levels and greater prevalence of atopic eczema when compared to the control group. There were deviations from the intended intervention, with some of the women in the intervention group continuing with the intervention through lactation. There were challenges with selective reporting of results. Although the outcome was assessed throughout infancy and early childhood, atopic dermatitis was not reported during the earlier time points.
- *Prospective cohort studies (Table 8)*: Similar to the RCTs, the cohort studies had serious flaws in the design and conduct of the studies:
 - At least one of the key confounders was not controlled for in all of the included studies.
 - Dietary data reflected dietary intake at a single time point during pregnancy and may not have reflected the intake during the entire period of pregnancy.
 - Outcome data were self-reported and potentially subjective as they were reported by the participants who were aware of the exposure.
 - Studies included in this body of evidence had co-exposures that may have been related to both exposure and outcome.
 - None of the included studies had a pre-registered data analysis plan.
- **Consistency** was graded strong for RCTs and moderate for prospective cohort studies.
 - *RCTs*: Both RCTs^{7,14} showed no relationship between avoiding cow milk product during pregnancy and risk of atopic dermatitis/eczema.
 - *Prospective cohort studies*: All five cohort articles^{4,5,22,26,28} reported no association between maternal cow milk product consumption and risk of atopic dermatitis/eczema. The only exception was a sub-group analysis in the U.S.-based study that showed that higher consumption of cow milk products was associated with a lower risk of atopic dermatitis/eczema in the child. Because of this inconsistency, this grading element for prospective cohort studies was rated moderate.
- **Directness** was graded moderate for the RCTs and limited for prospective cohort studies.
 - *RCTs*: Both trials^{7,14} were designed to assess the relationship between maternal cow milk product consumption and development of atopic diseases in infants and toddlers up to 18 months of age. In addition to the avoidance of cow milk products, the intervention group was also asked to avoid eggs. Hence, the findings might not have been attributable to cow milk product avoidance only.

For this reason, directness was graded moderate.

- *Prospective cohort studies*: While the articles^{4,5,22,26,28} included in this body of evidence focused on addressing the systematic review question considered, the data for these articles were from larger cohort studies that addressed associations between different exposures/outcomes.
- **Precision** was graded moderate for both RCTs and prospective cohort studies.
 - *RCTs*: Precision was considered moderate because both trials had a reasonable sample size (baseline n= 171¹⁴ and 212,⁷ respectively). However, power calculations were not reported in either of the studies. Neither of the studies unduly influenced the findings of this systematic review and removing a single study from this body of evidence would not likely change the conclusions.
 - *Prospective cohort studies*: Precision for the prospective cohort studies was also considered moderate because there were an adequate number of studies that were sufficiently powered to assess the association. Baseline sample size included at least 1,000 participants in all these cohorts. No single article unduly affected the findings of this systematic review and removing one study would not impact the overall conclusions.
- **Generalizability** was graded limited for both RCTs and prospective cohort studies.
 - *RCTs*: Both trials were conducted in Sweden in the 1980s. However, the studies provided very minimal information on age, race/ethnicity and other SES characteristics and thus the applicability of the findings to the U.S. population is unclear. Given the dearth of information, generalizability for RCTs was graded limited.
 - *Prospective cohort studies*: For two of the five cohorts (corresponding to three articles^{22,26,28}), 100 percent of participants were from Japan. Chatzi et al⁵ combined findings from two cohort studies, one based in Spain and another one in Greece. However, the race/ethnicity of the participants was not reported. The only U.S.-based study⁴ included in this body of evidence noted that most of the participants were White and were of moderate-to-high SES. Based on the characteristics of the participants in the cohorts, it is unclear if the findings would be representative of the U.S. mothers and hence generalizability was graded limited.

Egg

The following conclusion statement was supported by two RCTs^{7,14} and two cohorts^{4,28} and was graded moderate. Below, the individual grading elements are discussed separately for every study design.

“Moderate evidence indicates that lower or restricted consumption of egg during pregnancy does not reduce the risk of atopic dermatitis/eczema in the child.”

As outlined and described below, the body of evidence examining consumption of eggs during pregnancy and risk of atopic dermatitis/eczema in the child was assessed for the following elements used when grading the strength of evidence.

(Note: The same RCTs^{7,14} contributed to both (cow milk products and egg) bodies of evidence. Except for consistency, the individual grading elements for the RCTs are not discussed below and the readers are referred to the previous section on cow milk products.)

- **Risk of bias (Table 6, Table 8)** was graded moderate for the RCTs and limited for the prospective cohort studies.
 - *Prospective cohort studies:* There were serious flaws in the conduct of these studies,^{4,28} including lack of accounting of all the key confounders, subjective outcome reporting, a single point of exposure assessment during pregnancy, and lack of a pre-registered data analysis plan.
- **Consistency** was graded strong for the RCTs and prospective cohort studies.
 - *RCTs:* There was a strong consistency in the findings in that both RCTs^{7,14} showed no relationship between mother's avoidance of eggs during pregnancy and risk of atopic dermatitis/eczema.
 - *Prospective cohort studies:* Consistency for the prospective cohort studies^{4,28} was considered to be strong as both studies showed no association between egg consumption and the risk of atopic dermatitis/eczema. These findings were also consistent with the RCTs findings.
- **Directness** was graded moderate for the RCTs and limited for the prospective cohort studies.
 - *Prospective cohort studies:* While the articles^{4,28} included in this body of evidence focused on addressing the current systematic review question, the data for these articles were from larger cohort studies that addressed associations between different exposures and outcomes.
- **Precision** was graded moderate for the RCTs and limited for the prospective cohort studies.
 - *Prospective cohort studies:* Although the baseline sample size included at least 1,000 participants, there were only two cohort studies in this body of evidence. However, neither of them unduly affected the findings of this systematic review.
- **Generalizability** for the RCTs and the prospective cohort studies was graded limited.
 - *Prospective cohort studies:* The U.S.-based study⁴ included in this body of evidence noted that most of the participants were White and were of moderate-to-high SES. One other cohort study was conducted in Japan. In this study, more than two-thirds of the participants had ≥ 13 years of education and most had moderate-to-high SES. Based on the characteristics of the participants included in the cohort, it is unclear if the findings would be representative of U.S. mothers.

Fish

The following conclusion statement was supported by six prospective cohort studies^{5,11,13,24,25,28,31} and was graded "limited." The individual grading elements are discussed below.

"Limited evidence suggests that fish consumed during pregnancy does not increase the risk of atopic dermatitis/eczema in the child."

As outlined and described below, the body of evidence examining consumption of fish during pregnancy and risk of atopic dermatitis/eczema in the child was assessed for

the following elements used when grading the strength of evidence.

- **Risk of bias (Table 8)** was graded as limited as there were serious flaws in the design and conduct of the studies, which are described below:
 - At least one of the key confounders was not controlled for in all of the included studies.
 - Dietary data reflected dietary intake at a single time point during pregnancy and may not have reflected the intake during the entire period of pregnancy.
 - Outcome data were self-reported and potentially subjective as they were reported by the participants who were aware of the exposure.
 - Studies included in this body of evidence had co-exposures that may have been related to both exposure and outcome.
 - Two studies^{5,11} in this body of evidence had possible selection bias issues and also had a potential for bias in classification of exposures.
 - None of the included studies had a pre-registered data analysis plan.
- **Consistency** for this body of evidence was considered to be limited. Two^{11,31} of the seven articles reported that an increased consumption of fish during pregnancy was associated with a lower risk of atopic dermatitis and five articles^{5,13,24,25,28} (representing four cohorts) showed no association. The inconsistencies in findings across studies can be partly attributed to the methodological limitations that were noted in this body of evidence, including bias due to classification of exposure, deviations from intended exposures, and missing outcome data.
- **Directness** was graded as limited. While the articles^{5,11,13,24,25,28,31} included in this body of evidence focused on addressing the systematic review question, the data for these articles were from larger cohort studies that addressed associations between different exposures and outcomes.
- **Precision** was graded as moderate because there was an adequate number of studies that were sufficiently powered to assess the association. Sample sizes of most of the included studies in this body of evidence were at least 1,000 participants at baseline, with the exception of one study¹¹ that included 469 participants. No single article unduly affected the overall findings of this systematic review and removing one study would not impact the overall conclusions.
- **Generalizability** was graded limited. Two of the six cohorts (corresponding to three articles^{24,25,28}) were conducted in Japan. Chatzi et al⁵ combined findings from two cohort studies, one based in Spain and another one in Greece. However, the race/ethnicity of the participants was not reported. Two other European cohorts^{13,31} were included in this body of evidence. Specifically, Leermakers et al¹³ included 100 percent Dutch mothers from the Generation R cohort, noted that approximately 65 percent of the participants had 'higher' education. In the U.K.-based cohort, Willers et al³¹ did not report race/ethnicity, but noted that mothers left full-time education at a median age of 18.5 years. Finally, the cohort study conducted in the U.S. and Poland noted that women had ~15.7 years of education, but did not provide other characteristics including race/ethnicity. Based on the characteristics of the participants in the cohorts, it is unclear if the findings would be generalizable to the U.S. mothers and hence generalizability was graded limited.

Dietary patterns

The following conclusion statement was supported by five prospective cohort studies^{1,5,15,21,27,29} and was graded “limited.” The individual grading elements are discussed below.

“Limited evidence suggests that dietary patterns during pregnancy are not associated with risk of atopic dermatitis/eczema in the child.”

As outlined and described below, the body of evidence examining dietary patterns during pregnancy and risk of atopic dermatitis/eczema in the child was assessed for the following elements used when grading the strength of evidence.

- **Risk of bias (Table 8)** was graded as limited for the cohort studies because of the serious flaws in the design and conduct of the studies:
 - At least one of the key confounders was not controlled for in all of the included studies.
 - Dietary data reflected dietary intake at a single time point during pregnancy and may not have reflected the intake during the entire period of pregnancy.
 - Outcome data were self-reported and potentially subjective as they were reported by the participants who were aware of the exposure.
 - Studies included in this body of evidence had co-exposures that may have been related to both exposure and outcome.
 - One study⁵ in this body of evidence had possible selection bias issues and potential for bias in classification of exposures.
 - None of the included studies had a pre-registered data analysis plan.
- **Consistency** was graded as strong as all of the included articles consistently showed no association between maternal dietary patterns during pregnancy and risk of atopic dermatitis/eczema in the child.
- **Directness** was considered to be limited. While the articles included in this body of evidence focused on addressing the systematic review question, the data for these articles are from larger cohort studies that addressed associations between different exposures and outcomes.
- **Precision** was graded as moderate because of the adequate number of studies that were sufficiently powered to assess the association. Baseline sample sizes included at least 1,000 participants in most of the cohorts, except the Singapore-based cohort,¹⁵ which had a baseline sample size of 735. No single article unduly affected the findings of this systematic review and removing one study would not impact the overall conclusions.
- **Generalizability** was graded as limited. Of the studies conducted in Europe, two were from the same U.K.-based ALSPAC cohort,^{1,29} one from Spain/Greece,⁵ and one from the Netherlands.²⁷ The U.K.-based articles reported that most of the participants were White and possibly from mid-to-high SES. The other studies did not report the race/ethnicity of the mothers. The Singapore-based cohort study reported that all of the participants were Asian and the Japanese cohort study reporting that the 100 percent of the participants were from Japan. None of these studies were conducted in the U.S. Based on the characteristics of the participants in the cohorts, it is unclear if the findings would be representative of the U.S.

mothers.

Other foods

The bodies of evidence that assessed the relationship between:

- Peanuts, soybean, wheat/cereal, yogurt and probiotic milk products, and other foods (not commonly considered allergens, including meat, vegetables, and fruits) consumed during pregnancy,
- Cow milk products and eggs restricted during both pregnancy and lactation,
- Cow milk products restricted during lactation,

and risk of atopic dermatitis/eczema in the child were rated 'grade not assignable' for one or more of the following reasons:

- a very small body of evidence, usually less than two studies,
- heterogeneity in the findings,
- serious flaws in the design and conduct of the study, and
- limited generalizability of the findings to the U.S. population

Evidence synthesis – Allergic rhinitis

With 16 articles,^{1,3,4,7,8,14,15,17-20,29,31,34-36} there is a modest body of evidence available to examine the relationship between maternal diet during pregnancy and lactation and allergic rhinitis in the child.

Cow milk products

Pregnancy: Five studies, including two RCTs^{7,14} and three prospective cohort studies,^{3,4,18} assessed the relationship between consumption of cow milk products during pregnancy and risk of atopic dermatitis in the child. The RCTs were specifically designed to assess the relationship between the avoidance of cow milk products during pregnancy and allergic rhinitis, whereas the cohort studies assessed the association between maternal consumption of cow milk products during pregnancy and allergic rhinitis in the child. Two RCTs showed that there was no relationship between maternal avoidance of cow milk during pregnancy and risk of allergic rhinitis in the child. A large Norway-based cohort study³ (baseline n=40,614) showed that higher consumption of probiotic milk and yogurt during pregnancy was associated with a lower risk of rhinoconjunctivitis. Similarly, the U.S.-based cohort study⁴ showed that higher intake of milk during the first trimester was associated with a lower risk of allergic rhinitis in the child and this association was primarily seen among those without parental atopy. There was no association between maternal milk consumption during the second trimester and risk of allergic rhinitis. On the other hand, a Denmark-based cohort study¹⁸ (baseline n=61,909) noted that high intake of low-fat yogurt (> 1 serving per day vs. none) during pregnancy was associated with a greater risk of self-reported allergic rhinitis diagnosis in the child.

Pregnancy and lactation: A Japanese RCT,⁸ conducted in high-risk families, randomized mothers to consume hypoallergenic formula and asked mothers in the intervention group to avoid cow milk products during late pregnancy and lactation. Results showed no difference in the prevalence of overall allergies (including allergic

rhinitis, asthma and atopic eczema) between children of the intervention and control group mothers and there was no difference in allergic rhinitis between groups at any age. The three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria. The findings from these studies are presented in **Table 4**. However, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: No other studies assessed the relationship between maternal consumption of cow milk products during lactation and risk of allergic rhinitis in the child.

Egg

Pregnancy: Three studies, including two RCTs^{7,14} and one cohort study,⁴ assessed the relationship between maternal egg consumption/avoidance during pregnancy and risk of allergic rhinitis in the child. Specifically, the two trials^{7,14} conducted in Sweden that randomized mothers to avoid consumption of eggs during pregnancy (in addition to avoiding milk products) showed no relationship between an avoidance diet and risk of allergic rhinitis. These findings were in line with the results of the U.S.-based cohort study,⁴ which also showed no association between maternal consumption of eggs during pregnancy and risk of allergic rhinitis in the child at 7.9 years.

Pregnancy and lactation: Three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: No other studies assessed the relationship between maternal consumption of eggs during lactation and risk of allergic rhinitis in the child.

Fish

Pregnancy: Two cohort studies^{19,31} assessed the association between maternal fish consumption during pregnancy and risk of allergic rhinitis. In the U.K.-based cohort study,³¹ the authors reported that higher oily fish consumption (≥ 1 portion per week vs. never) was associated with a lower risk of doctor confirmed hay fever (allergic rhinitis). However, maternal oily fish consumption during pregnancy was not associated with hay fever (allergic rhinitis) in the child when the outcome was reported as “current hay fever medication” or “ever hay fever”. In a large Denmark-based cohort study,¹⁹ maternal fish intake during pregnancy was not associated with “ever prescribed” allergic rhinitis (as described by the study). However, lower fish intake, when compared to higher fish intake, during pregnancy was associated with a reduced risk of self-reported allergic rhinitis diagnosis in the child (P for trend=0.01).

Lactation: None of the studies assessed the association between maternal fish consumption during lactation and risk of allergic rhinitis in the child.

Peanut, tree nut and seed

Pregnancy: A U.S.-based cohort⁴ (baseline n=2,128) and a Denmark-based cohort study¹⁷ (baseline n=61,908) assessed the association between maternal peanut consumption during pregnancy and risk of allergic rhinitis in the child. The U.S.-based cohort study showed no association between maternal peanut consumption during the first and second trimesters and allergic rhinitis risk. The Denmark-based cohort study¹⁷ reported no association between maternal peanut (and pistachio) consumption during pregnancy and self-reported allergic rhinitis diagnosis. However, maternal consumption of peanuts (and pistachios) (1 time per month and 2-3 times per month

vs. never) during pregnancy was associated with lower odds of “ever prescribed” allergic rhinitis (as described in the study) in the child (P for trend=0.001).

The Denmark-based cohort study¹⁷ also assessed the association between maternal tree nut consumption and risk of allergic rhinitis in the child and found no association.

Pregnancy and lactation: The three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: None of the studies assessed an association between maternal peanut, tree nut, seed consumption during lactation and risk of allergic rhinitis in the child.

Soy

Pregnancy: The U.S.-based cohort study,⁴ found no association between maternal soy consumption during pregnancy and risk of allergic rhinitis in the child.

Pregnancy and lactation: Three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: None of the studies assessed the relationship between maternal soybean consumption during lactation and risk of allergic rhinitis in the child.

Wheat

Pregnancy: Bunyavanich et al,⁴ the U.S.-based cohort study, showed no association between maternal wheat consumption during both the first and second trimesters and risk of allergic rhinitis in the child in mid-childhood.

Pregnancy and lactation: The three articles³⁴⁻³⁶ from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: None of the studies assessed the relationship between maternal wheat consumption during lactation and allergic rhinitis in the child.

Dietary patterns

Pregnancy: Three articles from two cohort studies^{1,15,29} assessed the association between maternal DPs and risk of allergic rhinitis in the child. As noted below, studies assessed a variety of DPs:

1. Vegetable, fruit, and white rice DP, Seafood and noodles DP, and Pasta, cheese and processed meat DP¹⁵
2. Mediterranean diet score¹
3. Health conscious DP, Traditional DP, Processed DP, Vegetarian DP and Confectionary DP²⁹

Despite the heterogeneity in the DPs, none of the maternal DPs were associated with the risk of allergic rhinitis in the child.

Lactation: There were no studies that assessed the relationship between maternal DPs during lactation and allergic rhinitis risk in the child.

Other foods

Pregnancy: A Denmark-based cohort study²⁰ (baseline n=60,465) reported that higher

consumption of artificially-sweetened carbonated soft drinks during pregnancy was associated with higher risk of self-reported childhood allergic rhinitis diagnosis compared to lower consumption (P for trend=0.01). No association was noted for other types of beverage consumption and allergic rhinitis risk in the child.

Lactation: There were no studies that assessed the relationship between maternal consumption of other foods during lactation and risk of allergic rhinitis in the child.

Assessment of the evidence^{viii}

Egg

The following conclusion statement was supported by two RCTs^{7,14} and one cohort study⁴ and was graded moderate. Below, the individual grading elements are discussed separately for every study design.

“Moderate evidence indicates that lower or restricted consumption of eggs during pregnancy does not reduce the risk of allergic rhinitis in the child.”

As outlined and described below, the body of evidence examining consumption of eggs during pregnancy and risk of allergic rhinitis in the child was assessed for the following elements used when grading the strength of evidence.

- **Risk of bias** was graded as moderate for the RCTs (**Table 6**) and limited for the cohort studies (**Table 8**).
 - *RCTs:* The two RCTs included in this body of evidence had notable flaws, as described below:
 - Falth-Magnusson et al⁷ reported issues with adherence to the assigned intervention. There was differential adherence to the intervention: 79 of the 104 mothers randomized to the intervention group adhered to the cow milk- and egg-free diet and provided follow-up data on their children at 18 months, while 102 of the 108 women randomized to control group adhered to the standard diet and provided follow-up data on their children at 18 months.
 - Lilja et al¹⁴ reported potential issues with randomization with mothers in the intervention group reporting significantly higher IgE levels and greater prevalence of atopic eczema when compared to the control group. There were deviations from the intended intervention with some of the women in the intervention group continuing with the intervention through lactation. There were challenges with selective reporting of results. Although outcome was assessed throughout infancy and early childhood, atopic dermatitis was not reported at individual time points.
 - *Prospective cohort study:* Similar to the RCTs, the cohort study⁴ had serious flaws in the design and conduct of the study:
 - At least one of the key confounders was not controlled for in the cohort

^{viii} A detailed description of the methodology used for grading the strength of the evidence is available on the NESR website: <https://nesr.usda.gov/2020-dietary-guidelines-advisory-committee-systematic-reviews> and in Part C of the following reference: Dietary Guidelines Advisory Committee. 2020. *Scientific Report of the 2020 Dietary Guidelines Advisory Committee: Advisory Report to the Secretary of Agriculture and the Secretary of Health and Human Services*. U.S. Department of Agriculture, Agricultural Research Service, Washington, DC.

study.

- Outcome data were self-reported and potentially subjective as they were reported by the participants who were aware of the exposure.
- The study did not have a pre-registered data analysis plan.
- **Consistency** was graded as strong for the RCTs and grade not assignable for the prospective cohort study.
 - *RCTs*: There was a strong consistency in the findings. Both RCTs^{7,14} showed no relationship between avoidance of egg during pregnancy and risk of allergic rhinitis in the child.
 - *Prospective cohort study*: Consistency could not be assessed since only one prospective cohort study was included in this body of evidence.
- **Directness** was graded strong for the RCTs and limited for the prospective cohort study.
 - *RCTs*: Both trials^{7,14} were designed to assess the relationship between maternal avoidance of egg during pregnancy and development of atopic diseases in infants and toddlers up to 18 months of age.
 - *Prospective cohort study*: Although the study⁴ focused on addressing the systematic review question, this study is part of the larger Project Viva cohort that addressed associations between different exposures and outcomes.
- **Precision** was graded moderate for the RCTs and limited for the prospective cohort study.
 - *RCTs*: Precision was considered moderate because both trials had a reasonable sample size (baseline n= 171¹⁴ and 212⁷). However, power calculations were not reported in either of the studies. Neither of the studies unduly influenced the findings of this systematic review and removing a single study from this body of evidence would not likely change the conclusions.
 - *Prospective cohort study*: Precision for the prospective cohort study was considered to be limited because only one study was included in this body of evidence.
- **Generalizability** was graded limited for both the RCTs and the prospective cohort study.
 - *RCTs*: Both trials were conducted in Sweden in the 1980s. However, the studies provided very minimal information on maternal age, race/ethnicity and other socioeconomic characteristics and thus applicability of the findings to the U.S. population is unclear. Given the dearth of information, generalizability for RCTs was graded limited.
 - *Prospective cohort study*: Although the study was conducted in the U.S., the participants were predominantly White and were of mid-to-high SES. Based on the characteristics of the participants in the cohorts, it is unclear if the findings would be representative of U.S. mothers and hence generalizability was graded limited.

Dietary patterns

The following conclusion statement was supported by three articles^{1,15,29} and was graded “limited.” The individual grading elements are discussed below.

“Limited evidence suggests that dietary patterns during pregnancy are not associated with the risk of allergic rhinitis in the child.”

As outlined and described below, the body of evidence examining dietary patterns during pregnancy and risk of allergic rhinitis in the child was assessed for the following elements used when grading the strength of evidence.

- **Risk of bias (Table 8)** was graded as limited for the prospective cohort studies because of the serious flaws in the design and conduct of the studies, as described below:
 - At least one of the key confounders was not controlled for in all of the included studies.
 - Dietary data reflected dietary intake at a single time point during pregnancy and may not have reflected intake during the entire period of pregnancy.
 - Outcome data were self-reported and potentially subjective as they were reported by the participants who were aware of the exposure.
 - None of the included studies had a pre-registered data analysis plan.
- **Consistency** was graded as strong since all of the included studies consistently showed no association between maternal DPs and risk of allergic rhinitis in the child.
- **Directness** was graded as limited. While the articles included in this body of evidence focused on addressing the systematic review question, the data are from larger cohort studies that address associations between different exposures and outcomes.
- **Precision** was considered moderate because of the adequate number of studies that were sufficiently powered to assess the association. The two U.K.-based articles^{1,29} (from the same ALSPAC cohort) had a sample size of at least 1,000 participants at baseline, and the Singapore-based cohort¹⁵ had a baseline sample size of 735. No single cohort unduly affected the findings of this systematic review and removing one study would not impact the overall conclusions.
- **Generalizability** was graded as limited. The two articles that were from the same U.K.-based ALSPAC cohort^{1,29} reported that most of the participants were White and were of mid-to-high SES. The Singapore-based cohort study reported that a majority of the participants were Chinese (approximately 59 percent). None of these studies were conducted in the U.S. Based on the characteristics of the participants in the included studies, it is unclear if the findings would be representative of the U.S. mothers and hence generalizability was graded limited.

Other foods

The bodies of evidence that assessed the relationship between:

- Cow milk products (fermented or non-fermented) consumed during pregnancy, or during both pregnancy and lactation,
- Fish, peanuts, tree nuts, soybean, wheat, and foods not commonly considered

to be allergens, such as meat, vegetables, and fruits consumed during pregnancy,

and risk of allergic rhinitis in the child were rated ‘grade not assignable’ for one or more of the following reasons:

- a very small body of evidence, usually less than two studies,
- heterogeneity in the findings,
- serious flaws in the design and conduct of the study, and
- limited generalizability of the findings to the U.S. population.

Evidence synthesis – Asthma

With 20 included articles,^{1-4,6,8,9,17-20,27,29-34,36,38} including two RCTs^{8,34,36} and nine prospective cohort studies,^{1-4,6,8,9,17-20,27,29-34,36,38} there is a substantial body of evidence available to examine the relationship between maternal diet during pregnancy and/or lactation and asthma in the child (**Table 5**).

Cow milk products

Pregnancy: Four prospective cohort studies^{3,4,18,32} assessed the association between maternal cow milk product consumption and risk of asthma. Of these, two European cohort studies showed no association between maternal cow milk product consumption (i.e. probiotic milk and yogurt,³ dairy³²) and asthma risk in children.

Two other studies reported a significant association, at least in certain sub-groups. Specifically, the U.S.-based cohort study⁴ showed that a higher consumption of milk during the first trimester was associated with a lower asthma risk at 7.9 years. However, there was no association between maternal milk intake second trimester and subsequent asthma risk in the child. The Denmark-based cohort study¹⁸ showed that dairy product and milk intake during pregnancy was not associated with childhood asthma. The association between yogurt intake and asthma risk was mixed. Higher consumption of maternal low-fat yogurt intake (vs. lower intake) during pregnancy was associated with a greater risk (P for trend=0.03) for “ever admitted” asthma (as described in the study) in the child, whereas higher maternal full-fat yogurt intake during pregnancy, compared to lower intake, was associated with a reduced risk (P for trend=0.01) for “ever prescribed asthma” (as described in the study) in the child.

Pregnancy and Lactation: One Japan-based RCT⁸ showed no association between maternal avoidance of cow milk products during pregnancy and lactation and risk of asthma in children. Two articles^{34,36} from a single U.S. trial met the inclusion criteria. The findings from these studies are presented in **Table 5**. However, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: One Finland-based prospective cohort study³⁸ assessed the association between maternal milk and milk product consumption during lactation (3 months postpartum) and asthma risk in the child at 5 years and reported no association.

Egg

Pregnancy: Two studies, a U.S.-based cohort study with a baseline sample size of 2,128⁴ and U.K.- based study with a baseline sample size of 1,715,^{4,32} assessed the

association between maternal egg consumption during pregnancy and risk of asthma. Neither of the studies showed an association between maternal egg consumption during pregnancy and risk of asthma in children.

Pregnancy and lactation: Two articles^{34,36} from a single U.S. trial met the inclusion criteria; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: There were no studies that assessed the relationship between maternal egg consumption during lactation and risk of asthma in the child.

Fish

Pregnancy: Three European cohort studies (with a baseline sample size of 28,936 in the Denmark-based study,¹⁹ 3,963 in the Netherlands-based study,³² and 897 in the Ireland-based study³⁰) assessed the association between maternal fish consumption during pregnancy and risk of asthma in children. Two of these studies^{30,32} showed no association with the risk of asthma in children. In the third study,¹⁹ fish intake during pregnancy was not associated with the risk of “ever admitted” asthma (as described in the study) or current asthma at 7 years. However, no fish intake (vs. high fish intake) during pregnancy was associated with a higher risk of “ever prescribed asthma” (as described in the study) in the child.

Lactation: One Finland-based prospective cohort study³⁸ assessed the association between maternal fish consumption during lactation (3 months postpartum) and asthma risk in the child at 5 years and reported no association.

Peanut, tree nut and seed

Pregnancy: Three prospective cohort studies assessed the association between peanut/nut consumption during pregnancy and risk of asthma in the child. The evidence was mixed. Specifically, the Danish cohort study¹⁷ reported that higher peanut (and pistachio) consumption, compared to lower consumption, was associated with a reduced risk (P for trend=0.002) of “ever admitted” asthma (as described by the study). The Netherlands-based study,³² however, showed that higher nut product (including peanut butter) consumption was associated with a higher risk of childhood asthma at 3-8 years, when compared to lower intake. In the U.S.-based study⁴, peanut consumption during the first or second trimesters was not associated with the risk of asthma in the child.

The Denmark-based cohort study¹⁷ also assessed the association between maternal tree nut consumption during pregnancy and asthma. Higher tree nut consumption, compared to lower consumption, was associated with a reduced risk (P for trend=0.0003) of “ever prescribed” asthma (as described by the study) in the child. However, the Netherlands-based study³² noted that consumption of nuts (including tree nuts, peanuts, almonds, Brazil nuts, cashews, macadamia nuts, pistachios) was not associated with the risk of asthma in children.

There were no studies that showed an association between maternal seed consumption during pregnancy and risk of asthma in the child.

Pregnancy and lactation: Two articles^{34,36} from a single U.S. trial met the inclusion criteria for asthma; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: None of the studies assessed an association between maternal peanut, tree

nut, or seed consumption during lactation and risk of asthma in the child.

Soy

Pregnancy: The only prospective cohort study⁴ that assessed the relationship between maternal soybean consumption during pregnancy and risk of asthma in childhood showed no association.

Pregnancy and lactation: Two articles^{34,36} from a single U.S. trial met the inclusion criteria for asthma; however, they were not considered in evidence synthesis, grading, or when drawing conclusions for the reasons described above (p. 31).

Lactation: No other studies assessed the relationship between maternal soybean consumption during lactation and risk of asthma in the child.

Dietary Patterns

Pregnancy: Four cohort studies^{1,6,9,27,29} that assessed an association between maternal DPs and risk of asthma in the child. As noted below, studies assessed a variety of DPs (as described below):

1. Healthy Eating Index (HEI)⁶
2. Dietary Inflammatory Index (DII)^{6,9}
3. Diet quality score²⁷
4. Mediterranean diet score¹
5. Health conscious DP, Traditional DP, Processed DP, Vegetarian DP and Confectionary DP²⁹

Despite the heterogeneity in DPs, four articles that assessed the maternal DPs during pregnancy showed no association with the risk of asthma in the child. The only exception was the Irish study⁶ that showed that lower diet quality, assessed using HEI and DII, was associated with a higher risk of asthma.

Lactation: There were no studies that assessed the relationship between maternal DPs during lactation and asthma risk in the child.

Other foods

Pregnancy: Seven articles assessed the relationship between maternal consumption of other foods such as vegetables,^{2,5,23,30-32} fruits,^{2,31,32} wheat/whole grains,^{4,31} and asthma risk and noted the following:

- Vegetables: Of the four prospective cohort studies^{2,30-32} that assessed the association between maternal vegetable consumption during pregnancy and risk of asthma, none showed an association with asthma risk. All four studies were conducted in Europe and had a baseline sample size of at least 1,000 participants (except one study³⁰ with a baseline sample size of 897).
- Fruits: Three prospective cohort studies^{2,30-32} assessed the association between maternal fruit consumption during pregnancy and risk of asthma in children. Specifically, the U.K.-based cohort study reported no association between maternal total fruit consumption during pregnancy and risk of asthma at 5 years of age.³¹ However, consumption of apples during pregnancy was associated with a lower risk of asthma in the child. In the second study, maternal fruit consumption was not associated with overall asthma risk from 3-8 years of age.³² However, the study noted one significant association between maternal fruit consumption and steroid

use at 6 years of age.³² Another U.K.-based study showed no association between total fruit intake and risk of asthma in the child at 7.5 years.²

- **Wheat/whole grain:** Two prospective cohort studies assessed the association between maternal wheat/whole grain consumption and asthma risk in the child and neither of the studies showed an association.^{4,31} (Note: Whole grain included whole grains, wholemeal bread, bran flakes/sultana bran/all bran, shredded wheat/Weetabix, muesli, porridge, and brown rice).
- **Other beverages:** Two prospective cohort studies assessed the association between maternal beverage consumption during pregnancy and risk of asthma. Specifically, the U.S.-based study³³ noted that a higher maternal consumption of sugar-sweetened beverages averaged across the first and second trimesters of pregnancy was associated with an increased odds of asthma in the child at 7.7 years, compared to low consumption. The Danish cohort study noted that higher maternal consumption of artificially-sweetened carbonated (P for trend=0.01) and non-carbonated soft drink intake (P for trend=0.001) during pregnancy was associated with a higher risk of “ever prescribed” asthma in childhood (as described in the study), compared with lower intake. However, sugar-sweetened soft drink consumption during pregnancy was not associated with the risk of childhood asthma.
- **Margarine/low fat spread:** One study that assessed the relationship between maternal consumption of margarine/low fat spread during pregnancy and risk of asthma in the child found no association.³¹

Lactation: Margarine/oils/industrial fats/butter and butter-spreads/meat and meat products: One Finnish prospective cohort study³⁸ assessed the association between maternal consumption of margarine, oils, industrial fat (as reported in the study), meat and meat products during lactation and asthma risk in the child. The study reported that higher maternal margarine consumption at 3 months postpartum, compared to no intake, was associated with higher risk of asthma at 5 years. However, there was no association between maternal consumption of oils, industrial fats, butter and butter-spreads, meat and meat products and asthma risk in the child.

Assessment of the evidence^{ix}

Cow milk products

The following conclusion statement was supported by four prospective cohort studies^{3,4,18,32} and was graded “limited.” The individual grading elements are discussed below.

“Limited evidence suggests that a lower consumption of cow milk products during pregnancy does not reduce risk of asthma in the child.”

As outlined and described below, the body of evidence examining consumption of cow milk products during pregnancy and risk of asthma in the child was assessed for the

^{ix} A detailed description of the methodology used for grading the strength of the evidence is available on the NESR website: <https://nesr.usda.gov/2020-dietary-guidelines-advisory-committee-systematic-reviews> and in Part C of the following reference: Dietary Guidelines Advisory Committee. 2020. *Scientific Report of the 2020 Dietary Guidelines Advisory Committee: Advisory Report to the Secretary of Agriculture and the Secretary of Health and Human Services*. U.S. Department of Agriculture, Agricultural Research Service, Washington, DC.

following elements used when grading the strength of evidence.

- **Risk of bias (Table 8)** was graded as limited.
 - The cohort studies^{3,4,18,32} had serious flaws in the design and conduct of the study:
 - At least one of the key confounders was not controlled for in all of the cohort studies.
 - Two studies^{18,32} in this body of evidence had possible selection bias issues.
 - Studies included in this body of evidence had co-exposures that may have been related to both the exposure and the outcome.
 - Outcome data were self-reported and potentially subjective as they were reported by the participants who were aware of the exposure.
 - Studies did not have a pre-registered data analysis plan. There was a high likelihood of selective reporting of the analysis in at least one study.¹⁸
- **Consistency** was graded as moderate.
 - Two prospective cohort studies^{3,32} reported no association between maternal cow milk product consumption during pregnancy and risk of asthma. The third study⁴ reported an association between maternal milk consumption during the first trimester only (and not the second trimester) and asthma risk. The fourth study¹⁸ reported mixed findings, with higher consumption of low-fat yogurt associated with a greater risk of asthma and higher consumption of high-fat yogurt associated with lower risk of asthma. The inconsistency in findings can be partially attributed to the methodological issues, as described in the risk of bias section.
- **Directness** was graded as limited.
 - Although the prospective cohort studies^{3,4,18,32} focused on addressing the systematic review question, these studies were part of larger cohort studies that addressed associations between different exposures/outcomes.
- **Precision** was graded as limited.
 - Precision for the prospective cohort studies was considered to be limited. There were four prospective cohort studies that were sufficiently powered to assess the association. Baseline sample sizes included at least 1,000 participants in all these cohorts. No single cohort unduly affected the findings of this systematic review and removing one study would not impact the overall conclusions.
- **Generalizability** was graded as limited.
 - One study⁴ was conducted in the U.S. and participants were predominantly White and from mid-to-high SES. The rest of the studies^{3,18,32} included in this body of evidence were conducted in Europe. While the studies did not report on race/ethnicity, the three European studies noted that the majority of the participants had some college education. Based on the characteristics of the participants in these cohorts, it is unclear if the findings would be representative of the U.S. mothers and hence generalizability was graded limited.

Egg

The following conclusion statement was supported by two prospective cohort studies^{4,32} and was graded “limited.” The individual grading elements are discussed below.

“Limited evidence suggests no relationship between eggs consumed during pregnancy and risk of asthma in the child.”

As outlined and described below, the body of evidence examining consumption of eggs during pregnancy and risk of asthma in the child was assessed for the following elements used when grading the strength of evidence.

- **Risk of bias (Table 8)** was graded as limited for cohort studies. Both studies^{4,32} had serious flaws in the design and conduct of the study:
 - At least one of the key confounders was not controlled for in both studies.
 - The Netherlands study³² had possible selection bias issues.
 - There were issues with missing data in both of the studies.
 - Outcome data were self-reported and potentially subjective as they were reported by the participants who were aware of the exposure.
 - Studies did not have a pre-registered data analysis plan.
- **Consistency** was graded as strong as both of the included studies consistently showed no association between maternal egg consumption during pregnancy and risk of asthma in the child.
- **Directness** was graded as limited. While the articles included in this body of evidence focused on addressing the systematic review question, the data for these articles are from larger cohort studies that addressed associations between different exposures/outcomes.
- **Precision** was limited. Although both studies had a sample size of at least 1,000 participants at baseline, there were only two studies included in this body of evidence. Neither study unduly affected the findings of this systematic review; removing one study would not impact the overall conclusions.
- **Generalizability** was graded as limited. One study⁴ was conducted in the U.S. with predominantly White participants who were of mid-to-high SES. The Dutch study³² noted that approximately 22 percent had low maternal education, although the study did not define “low.” There was no information on the race/ethnicity of the participants. Based on the characteristics of the participants in the included studies, it is unclear if the findings would be representative of U.S. mothers and hence generalizability was graded limited.

Fish

The following conclusion statement was supported by three prospective cohort studies^{19,30,32} and was graded “limited.” The individual grading elements are discussed below.

“Limited evidence suggests no relationship between fish consumed during pregnancy and risk of asthma in the child.”

As outlined and described below, the body of evidence examining consumption of fish during pregnancy and risk of asthma in the child was assessed for the following elements used when grading the strength of evidence.

- **Risk of bias (Table 8)** was graded limited for the prospective cohort studies because of the serious flaws in the design and conduct of the studies, as described below:
 - At least one of the key confounders was not controlled for in all of the cohort studies.
 - All three studies in this body evidence had possible selection bias issues.
 - Studies included in this body of evidence had co-exposures that may have been related to both exposure and outcome.
 - Outcome data were self-reported and potentially subjective as they were reported by the participants who were aware of the exposure.
 - Studies did not report a pre-registered data analysis plan. There was a possibility of selective reporting of the analysis in at least one of the three studies.³⁰
- **Consistency** was graded as moderate as two of the included studies consistently showed no association between maternal fish consumption during pregnancy^{30,32} and risk of asthma. In the third study, fish intake during pregnancy was not associated with risk of “ever admitted” asthma or current asthma at 7 years.¹⁹ However, no fish intake (vs. high fish intake) during pregnancy was associated with a higher risk of “ever prescribed” asthma.
- **Directness** was graded as limited. While the articles included in this body of evidence focused on addressing the systematic review question, the data for these articles are from larger cohort studies that addressed associations between different exposures/outcomes.
- **Precision** was considered moderate because there was an adequate number of studies that was sufficiently powered to detect the association. The sample sizes in all three studies were reasonable and ranged from 897³⁰ to 28,936 participants¹⁹ at baseline. No single cohort unduly affected the overall findings of this systematic review and removing one study would not impact the overall conclusions.
- **Generalizability** was graded as limited. None of these studies were conducted in the U.S. These European cohort studies did not report the race/ethnicity of the participants; however, the Viljoen et al³⁰ reported that all participants were 100 percent Ireland-born. Based on the characteristics of the participants in the included studies, it is unclear if the findings would be representative of U.S. mothers and hence generalizability was graded limited.

Other foods

The bodies of evidence that assessed the relationship between:

- Cow milk products consumed during both pregnancy and lactation, or lactation,
- Maternal dietary patterns or peanuts, tree nuts, soybean, and other foods such as wheat/whole grains, vegetables, fruits, beverages, and margarine consumed

during pregnancy,

- Fish, and other foods, such as margarine, oil, butter and butter-spreads, industrial fat, meat, and meat products consumed during lactation,

and risk of asthma in the child were rated 'grade not assignable' for one or more of the following reasons:

- a very small body of evidence, usually two studies or less,
- heterogeneity in the findings,
- serious flaws in the design and conduct of the study, and
- limited generalizability of the findings to the U.S. population.

Publication bias is an important consideration in this systematic review and can be perceived to be a concern because of the fewer number of studies within each intervention/exposure-outcome relationships. However, this systematic review included studies that reported null findings in both relatively small and large studies, which suggests that publication bias may be less of a concern in this body of evidence.

Research recommendations

- Include well-designed RCTs and prospective cohort studies that assess the relationship between maternal diet and risk of atopic dermatitis/eczema, food allergies, allergic rhinitis and asthma.
- Assess intervention/exposure at multiple time points during pregnancy and/or during lactation.
- Adjust for key confounding factors in observational studies, including maternal age, race/ethnicity, socioeconomic status, smoking, family history of atopic allergic diseases, gestational age at birth, birth weight, mode of delivery, human milk feeding practices (intensity, duration), types of complementary foods and beverages and timing of its introduction, urban/rural environment, animals/pets/farming exposure; sex, maternal substance use (alcohol, drug use), and Indoor and outdoor environment.
- Include diverse populations with varying age groups and different racial/ethnic and socioeconomic backgrounds.

Study and Participant Characteristics	Intervention/Exposure and Outcomes	Results	Confounding, Study Limitations, and Summary of Findings
	<p>Maternal dietary assessments at the first and second trimester visits were based on a validated 166-item semi-quantitative FFQ modified for pregnancy. The total servings per day of each major food allergen (peanut, milk, wheat, egg, and soy) were calculated by summing the servings per day of the foods on the FFQ containing these respective food allergens.</p> <p>Outcome:</p> <p>Food Allergy at ~7.9 y</p> <p>Outcome assessment methods:</p> <p>Sensitization to a food allergen was considered positive if the respective allergen sIgE level was 0.35 kU/L or more. Prescription of an epinephrine autoinjector was assessed with the question, “Has a health care professional, such as a doctor, physician assistant, or nurse practitioner, ever prescribed an EpiPen for your child?” A child was considered to have food allergy to peanut, milk, wheat, egg, and/or soy if he or she had a sIgE level of 0.35 kU/L or more to the particular food and EpiPen prescribed.</p>		<ul style="list-style-type: none"> • Pre-registered data analysis plan NR <p>Summary:</p> <p>Maternal intake of any major food allergens (peanuts, milk, egg, wheat or soy) in the 1st trimester or 2nd trimester was not associated with risk of food allergy in the child at 7.9 y.</p>
<p>Lack, 2003¹²; U.K. PCS, ALSPAC</p> <p>Baseline N=13,971 Analytic N=11,352</p>	<p>Food(s) or Food Group(s):</p> <p>Soybean meat consumption (yes/no)</p> <p>Assessed once at 32 wk gestation</p>	<p>Significant:</p> <p>Non-significant:</p> <p>Soybean meat consumption</p>	<p>Key confounders accounted for:</p> <p>None</p> <p>OFCs accounted for:</p>

Study and Participant Characteristics	Intervention/Exposure and Outcomes	Results	Confounding, Study Limitations, and Summary of Findings
<ul style="list-style-type: none"> • Age: NR • Race/Ethnicity: NR • SES: NR • Baseline characteristics NR by exposure 	<p>Outcome: Food allergy at 38 mo</p> <p>Outcome assessment methods: Children ≤38 mo who had peanut allergy on the basis of responses to questions about food avoidance and reactions to particular foods were identified. Affected children were also identified from responses to questions on the questionnaire regarding previous hospitalizations and clinical investigations. Forty-nine mothers of children who had a reaction to peanuts according to questionnaire responses were interviewed in detail over the telephone about the reaction. Children who were found to have had a reaction to peanuts (age range, four to six years) underwent skin testing and double-blind, placebo-controlled food challenge. Skin testing was performed with peanut (concentration, 1:20 [wt/vol] in 50 percent glycerol). A skin test was considered positive if it resulted in a palpable wheal at least 3 mm in diameter. Peanut food allergy at 4-6y confirmed by double-blind, placebo-controlled food challenge</p>	<p>Yes vs No (Ref): P=NS</p> <p>Only among those with positive peanut challenge: Yes vs No (Ref): P=NS</p>	<p>None</p> <p>Limitations:</p> <ul style="list-style-type: none"> • No key confounders controlled for • Exposure status and methods used to assess the exposure are not well defined. It is not clear what soybean meat included. • Potential for selection bias, since the participants that only responded to the allergy question in the questionnaire were included in the study • No information on deviation from intended exposure or on proportions and reasons for missing data across exposure groups • No pre-registered data analysis plan <p>Summary: Maternal soybean meat consumption during pregnancy was not associated with risk of peanut allergy at 4-6 y.</p>
Pregnancy and Lactation			
Randomized Controlled Trials			
Fukushima, 1997⁸; Japan RCT	Food(s) or Food Group(s):	<p>Significant: Note, CD had significantly higher odds of overall allergies vs MD at</p>	<p>Key confounders accounted for: Smoking, Family history, (CFB for aOR), Pets</p>

Study and Participant Characteristics	Intervention/Exposure and Outcomes	Results	Confounding, Study Limitations, and Summary of Findings
<p>Baseline N=350 Analytic N=283</p> <ul style="list-style-type: none"> Age: NR Race/Ethnicity: 100% from Japan SES: NR Significant differences by exposure (by design): HMF, CFB No differences by exposure: Smoking, Family history, BW, Pets ~76% had a positive history of allergy (i.e., both parents or one parent or sibling only had history of allergies) 	<ul style="list-style-type: none"> CD: Mothers instructed to consume >200mL/d cow milk, n=140 randomized, n=127 analyzed MD: Mothers instructed to consume >200mL/d a casein-free, hypoallergenic formula and to avoid cow milk and reduce consumption of cow milk products, n=140 randomized, n=102 analyzed AF: Mothers instructed to consume >200mL/d a casein-free, hypoallergenic formula and to avoid cow milk and reduce consumption of cow milk products, n=70 randomized, n=54 analyzed (Not randomized, no relevant comparisons included, except as co-variables in logistic regressions) <ul style="list-style-type: none"> Also supplemented with 1000 mg/d Ca <p>during late pregnancy through end of lactation up to 6 mo postpartum</p> <p>From birth to 6 mo, the infants in the MD and CD groups were exclusively HMF or mixed-fed with breast milk and casein-free, hypoallergenic formula when breast milk was insufficient. The infants in the AF group were mixed-fed with breast milk and a formula with similar whey:casein ratio as breastmilk for the corresponding 6 mo. Infants who were fed breast milk exclusively from birth to 4mo were excluded from the AF group.</p> <p>Dietary assessment methods:</p>	<p>12mo, but due to inclusion of asthma as part of the outcome, these results do not meet the NESR criteria</p> <p>Non-significant:</p> <p>Median total IgE levels at 4mo, P=NS</p> <ul style="list-style-type: none"> CD: 3.20 IU/mL MD: 3.36 IU/mL <p>Overall allergies at 24mo, P=NS</p> <ul style="list-style-type: none"> CD: aOR=1.75, 95% CI: (0.94, 3.25) MD: (Ref) <p>Note, odds of overall allergies NS at 6 and 18 mo. However, due to inclusion of asthma these results do not meet the NESR criteria</p>	<p>OFCs accounted for:</p> <p>None</p> <p>Limitations:</p> <ul style="list-style-type: none"> Randomization process NR MD still consumed cow milk products, but had lower intake than CD Attrition higher in MD group because women excluded from analysis if they consumed cow milk Proportions of missing data seem to differ, reasons for missingness NR Participants were aware of exposure status and outcomes were self-reported Pre-registered data analysis plan NR <p>Summary:</p> <p>Consuming diets replacing cow milk with casein-free hypoallergenic formula with reduced consumption of cow milk products from late pregnancy through lactation did not impact overall allergies, including atopic eczema, asthma and allergic rhinitis in the child.</p>

Study and Participant Characteristics	Intervention/Exposure and Outcomes	Results	Confounding, Study Limitations, and Summary of Findings
	<p>Daily food diary from late pregnancy until 6mo postpartum, recording the amount of casein-free, hypoallergenic formula, cow milk, cow milk products, eggs, meat, and soy products consumed.</p> <p>Outcome:</p> <p>Overall allergies (eczema, asthma, and/or allergic rhinitis) at 24mo</p> <p>Outcome assessment methods:</p> <p>Self-reported by questionnaire. Specific allergies defined when symptoms chronically lasted for more than a few weeks.</p> <p>Umbilical cord blood and venous blood obtained from all infants at birth and 4mo of age. Total IgE in serum was measured using a radioimmunoassay (RIA) kit. Cow milk-specific IgE level in serum was measured by the CAP-RAST method. Specific IgE (RAST) was considered positive when the level was more than 0.35UA/mL.</p>		
<p>Zeiger, 1989³⁵; U.S. RCT</p> <p>Baseline N=379 Analytic N=288</p> <p>Power analysis: Yes</p>	<p>Food(s) or Food Group(s):</p> <ul style="list-style-type: none"> Control: Mothers encouraged to follow standard diets during 3rd trimester of pregnancy and lactation, n=212 <ul style="list-style-type: none"> Cow milk-based whey infant formula provided for supplementation or weaning through 12 mo postpartum. <p>at least one of the family member (husband or child)</p>	<p>low intake of ≤ 2 dL/wk milk and ≤ 2 eggs/wk ($P < 0.0001$).</p> <p>Diet during lactation: Mothers that asked for information about diet during lactation were informed about a "low allergenic diet" regimen, allowing up to 2 dl of milk per day and two eggs per week. In the diet group, 10 mothers also continued to keep a strictly milk- and egg-free diet after delivery. The difference in consumption of these foods between the groups was statistically significant.</p> <p>Outcome:</p> <p>Probable rhinoconjunctivitis at 18mo</p> <p>Outcome assessment methods:</p> <p>All babies who demonstrated any signs and symptoms suggesting atopic disease or allergy before the age of 18 mo were examined by a senior pediatric allergist. The selection of examination was based on the information from the questionnaires, available case records, results of two skin prick tests and the result of a nurse visit at 18 mo. All babies demonstrating positive SPTs on any occasion were examined, as well as babies with a history of either otitis media, bronchitis, or pseudocroup on two or more occasions, and babies whose parents or the nurse had suspected eczema at any time. The aim of the physical examination at 18 mo</p>		<ul style="list-style-type: none"> • Differences in HMF duration and CFB could have influenced the outcome • Attrition of 15% still left >180 participants required by estimate from power calculation • Lost to follow-up was higher in the D group than the ND group • No pre-registered data analysis plan <p>Summary:</p> <p>Maternal avoidance of milk and eggs during 28wk gestation through delivery was not associated with probable rhinoconjunctivitis in the child at 18mo.</p>

Study and Participant Characteristics	Intervention/Exposure and Outcomes	Results	Confounding, Study Limitations, and Summary of Findings
	<p>was to score whether the child up to the age of that age had demonstrated definite, probable, possible, or no signs of atopic diseases. A question mark after atopic dermatitis points out that some but not all of the diagnostic features were present.</p>		
<p>Lilja, 1989¹⁴; Sweden Cluster RCT</p> <p>Baseline N=171 Analytic N=162</p> <ul style="list-style-type: none"> • Age: ~28.7y • Race/Ethnicity: NR • SES: NR • Characteristics reported with no difference by exposure <ul style="list-style-type: none"> ○ Smoking ○ Family history ○ HMF ○ CFB timing, types ○ Animal/Pets/Farming exposure <p>Women in this study had a history of respiratory allergy symptoms after exposure to animal danders (cat and dog) and/or tree or grass pollens</p>	<p>Food(s) or Food Group(s):</p> <ul style="list-style-type: none"> • High: Consumed “normal” amounts of hens’ egg and cows’ milk, n=83 • Reduced: Strictly reduced ingestion of egg and dairy products (milk, yogurt, butter, cheese, etc.), n=79 <ul style="list-style-type: none"> ○ Reduced A-Group: Women chose to continue reduced diet through 2mo postpartum (n=25) ○ Reduced B-Group: Women adhered to study design and stopped reduced diet after delivery (n=54) <p>from 28wk gestation until delivery (until 2mo postpartum for A-Group)</p> <p>Dietary assessment methods:</p> <p>Women were randomly assigned to groups. In reduced group, no foods obviously containing egg or cows’ milk were allowed, but small amounts of these foods, such as bread brushed with egg or ordinary margarines, were allowed.</p> <p>Outcome: Atopic disease: Atopic eczema</p>	<p>Significant:</p> <p>Non-significant:</p> <p>Rhinoconjunctivitis by 18mo</p> <ul style="list-style-type: none"> • There were no significant differences between any groups (High, Reduced, A-Group, B-Group) in cumulative prevalence of obvious, probable, or possible rhinoconjunctivitis. 	<p>Key confounders accounted for:</p> <p>Age, Race/Ethnicity, SES, Smoking, Family history, HMF, CFB, Pets</p> <p>OFCs accounted for:</p> <p>Child sex</p> <p>Limitations:</p> <ul style="list-style-type: none"> • There was a significantly higher incidence of atopic eczema and higher IgE levels before week 28 in the 'reduced' group. • Data <18mo measured but NR. • 4 pairs of twins included, but family relation is not accounted for in analyses. • Although a cluster RCT, it seems like the data analysis was conducted at the individual level. <p>Summary:</p> <p>Higher (vs reduced) intake of egg and dairy products during pregnancy did not impact child's rhinoconjunctivitis risk at 18 mo.</p>

Study and Participant Characteristics	Intervention/Exposure and Outcomes	Results	Confounding, Study Limitations, and Summary of Findings
	<p>Rhinoconjunctivitis at 2, 6, 12 and 18 mo</p> <p>Outcome assessment methods:</p> <p>All children were examined at 2, 6, 12, and 18 mo. The physicians who performed the physical examination at 18 mo were unaware of the mothers' diet during the trial and of previously performed SPT and in-vitro analyses in the mother and child. The cumulative incidence of signs of atopic diseases ≥ 18 mo was evaluated by a questionnaire and the physical examination into the following groups: obvious atopic, probable atopic, possible atopic, and the type of atopic symptom was noted.</p>		
Prospective Cohort Studies			
<p>Loo, 2017¹⁵; Singapore PCS, GUSTO</p> <p>Baseline N=735 Analytic N=620 (at 18 mo) and 576 (36 mo)</p> <ul style="list-style-type: none"> • Age: NR • Race/Ethnicity: <ul style="list-style-type: none"> ◦ Chinese: ~59% ◦ Malay: ~26% ◦ Indian: ~15% • SES: • Maternal Education: <ul style="list-style-type: none"> ◦ <12 y: ~38% ◦ ≥ 12 y college: ~62% 	<p>Food(s) or Food Group(s):</p> <p>Dietary pattern adherence</p> <ul style="list-style-type: none"> • VFR: Higher score indicated higher intakes of vegetables, fruit, and rice • SFN: Higher score indicated higher intakes of seafood and noodles • PCP: Higher score indicated higher intakes of pasta, cheese, and processed meat <p>at 26-28 wk gestation</p> <p>Dietary assessment methods:</p> <p>Dietary intake was assessed at 26-28 weeks of pregnancy which was conducted by trained clinical staff with the use of the 5-stage multiple pass</p>	<p>Significant:</p> <p>Non-significant:</p> <p>All dietary patterns at 18 mo and 3 y, P=NS</p>	<p>Key confounders accounted for:</p> <p>SES, Family history, Race/ethnicity</p> <p>OFCs accounted for:</p> <p>Sex</p> <p>Limitations:</p> <ul style="list-style-type: none"> • At least one key confounder not adjusted for • No information on potential co-exposures • Proportions of or reasons for missingness NR • Physician-diagnosis for eczema; women probably unaware of own dietary pattern.

Study and Participant Characteristics	Intervention/Exposure and Outcomes	Results	Confounding, Study Limitations, and Summary of Findings
<p>Reported but not tested by exposure: Family history, SES</p>	<p>interviewing technique. Dietary patterns were derived by principal component extraction with Varimax rotation on the 68 food groups. Three factors (i.e. dietary patterns) were retained</p> <p>Outcome:</p> <p>Rhinitis at 18 mo and 3 y</p> <p>Outcome assessment methods:</p> <p>“Rhinitis” was based on a positive response to the question “Has your child ever had sneezing, running nose, blocked or congested nose, snoring or noisy breathing during sleep or when awake that has lasted for 2 or more weeks duration?” Study team members called the participants who reported rhinitis to collect information on the number of episodes of rhinitis and the duration of each episode. A case prior to 18 mo required a single episode that lasted for at least 4 weeks or two or more episodes each lasting at least 2 weeks. New cases of rhinitis after 18 mo were defined by one or more episodes lasting at least 2 weeks.</p>		<ul style="list-style-type: none"> • Outcomes collected at 3, 6, 9, 12, 15, 18, 24, and 36 mo, but only 18, 36 mo reported because SPT data collected then • Although the outcome was based on diagnosed eczema, it was still self-reported • Mothers who participated in the study differed on the following characteristics from those that did not: race/ethnicity and maternal education levels • Pre-registered data analysis plan NR <p>Summary:</p> <p>Maternal consumption of any dietary pattern during 26-28 wk pregnancy was not associated with risk of rhinitis in the child at 18 mo or 3 y.</p>

METHODOLOGY

The NESR team used its rigorous, protocol-driven methodology to support the 2020 Dietary Guidelines Advisory Committee in conducting this systematic review.

NESR's systematic review methodology involves:

- Developing a protocol,
- Searching for and selecting studies,
- Extracting data from and assessing the risk of bias of each included study,
- Synthesizing the evidence,
- Developing conclusion statements,
- Grading the evidence underlying the conclusion statements, and
- Recommending future research.

A detailed description of the methodology used in conducting this systematic review is available on the NESR website: <https://nesr.usda.gov/2020-dietary-guidelines-advisory-committee-systematic-reviews>, and can be found in the 2020 Dietary Guidelines Advisory Committee Report, Part C: Methodology.^{xxii} This systematic review was peer reviewed by Federal scientists, and information about the peer review process can also be found in the Committee's Report, Part C. Methodology. Additional information about this systematic review, including a description of and rationale for any modifications made to the protocol can be found in the 2020 Dietary Guidelines Advisory Committee Report, Chapter 2. Food, Beverage, and Nutrient Consumption During Pregnancy and Chapter 3. Food, Beverage, and Nutrient Consumption During Lactation.

Below are details of the final protocol for the systematic review described herein, including the:

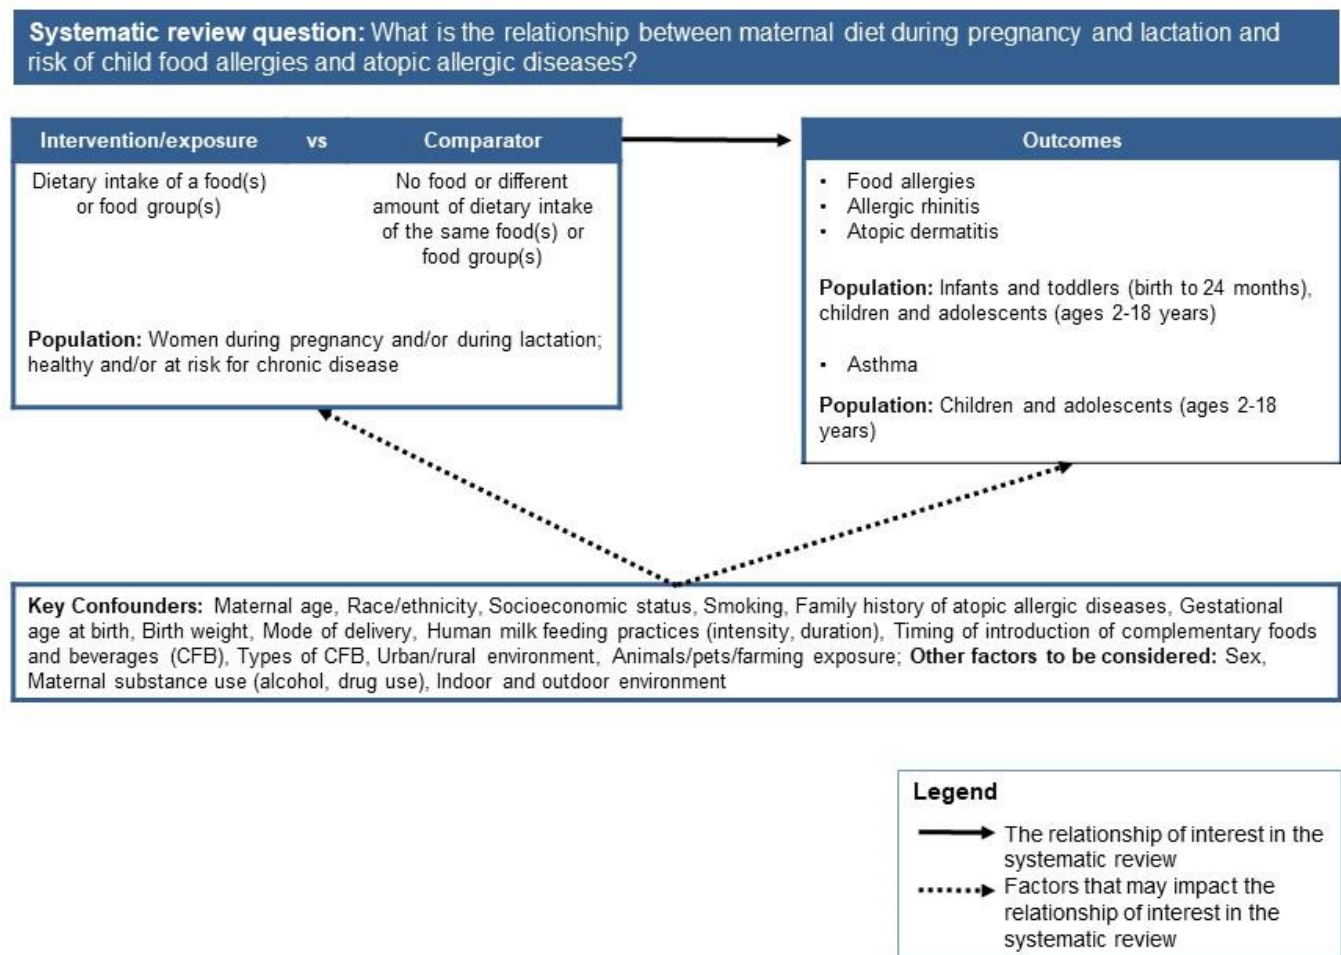

- Analytic framework
- Literature search and screening plan
- Literature search and screening results

ANALYTIC FRAMEWORK

The analytic framework (Figure 1: Analytic framework **Figure 1**) illustrates the overall scope of the systematic review, including the population, the interventions and/or exposures, comparators, and outcomes of interest. It also includes definitions of key terms and identifies key confounders considered in the systematic review. The inclusion and exclusion criteria that follow provide additional information about how parts of the analytic framework were defined and operationalized for the review.

^{xxii} Dietary Guidelines Advisory Committee. 2020. *Scientific Report of the 2020 Dietary Guidelines Advisory Committee: Advisory Report to the Secretary of Agriculture and the Secretary of Health and Human Services*. U.S. Department of Agriculture, Agricultural Research Service, Washington, DC.

LITERATURE SEARCH AND SCREENING PLAN

Inclusion and exclusion criteria

This table provides the inclusion and exclusion criteria for the systematic review. The inclusion and exclusion criteria are a set of characteristics used to determine which articles identified in the literature search were included in or excluded from the systematic review.

Table 9. Inclusion and exclusion criteria

Category	Inclusion Criteria	Exclusion Criteria
Study design	<ul style="list-style-type: none"> • Randomized controlled trials • Non-randomized controlled trials including quasi-experimental and controlled before-and-after studies • Prospective cohort studies • Retrospective cohort studies • Nested case-control studies 	<ul style="list-style-type: none"> • Uncontrolled trials • Case-control studies • Cross-sectional studies • Uncontrolled before-and-after studies • Narrative reviews • Systematic reviews • Meta-analyses
Intervention/exposure	<ul style="list-style-type: none"> • Dietary intake of a food(s) or food group(s) 	
Comparator	<ul style="list-style-type: none"> • Different amount of dietary intake of the same food(s) or food group(s) 	<ul style="list-style-type: none"> • No comparator
Outcomes	<ul style="list-style-type: none"> • Food allergies • Atopic dermatitis • Allergic rhinitis • Asthma (≥ 2 years old) 	<ul style="list-style-type: none"> • Food allergy when diagnosis was based solely on food allergen sensitization (i.e., skin prick test, or serum IgE measure) (i.e., without an oral food challenge or parental report of clinical history) • Asthma when diagnosis was based solely on report of wheeze
Date of publication	<ul style="list-style-type: none"> • January 1980 to January 2020 	<ul style="list-style-type: none"> • Articles published before January 1980 or after January 2020

Category	Inclusion Criteria	Exclusion Criteria
Publication status	<ul style="list-style-type: none"> Articles that have been peer-reviewed 	<ul style="list-style-type: none"> Articles that have not been peer-reviewed and are not published in peer-reviewed journals, including unpublished data, manuscripts, reports, abstracts, and conference proceedings
Language of publication	<ul style="list-style-type: none"> Articles published in English 	<ul style="list-style-type: none"> Articles published in languages other than English
Country^{xxiii}	<ul style="list-style-type: none"> Studies conducted in countries ranked as high or very high human development 	<ul style="list-style-type: none"> Studies conducted in countries ranked as medium or lower human development
Study participants	<ul style="list-style-type: none"> Human participants 	<ul style="list-style-type: none"> Non-human participants (e.g., animal or in-vitro models)
Life stage of study participants - intervention or exposure	<ul style="list-style-type: none"> Women during pregnancy OR women during both pregnancy and lactation, regardless of human milk feeding status Women during lactation who are exclusively or predominantly feeding human milk 	<ul style="list-style-type: none"> Studies conducted exclusively in non-lactating women or in lactating women who are not exclusively or predominantly feeding human milk.
Life stage of study participants - outcomes:	<p>Food allergies, atopic dermatitis, and allergic rhinitis:</p> <ul style="list-style-type: none"> Infants and toddlers (birth – 24 months) <p>All outcomes:</p> <ul style="list-style-type: none"> Children and adolescents (2 – 18 years) 	<p>Asthma:</p> <ul style="list-style-type: none"> Infants and toddlers (birth – 24 months) <p>All outcomes:</p> <ul style="list-style-type: none"> Adults (19 – 64 years) Older adults (65 years and older)

^{xxiii} The Human Development classification was based on the Human Development Index (HDI) ranking from the year the study intervention occurred or data were collected (UN Development Program. HDI 1990-2017 HDRO calculations based on data from UNDESA (2017a), UNESCO Institute for Statistics (2018), United Nations Statistics Division (2018b), World Bank (2018b), Barro and Lee (2016) and IMF (2018). Available from: <http://hdr.undp.org/en/data>). If the study did not report the year in which the intervention occurred or data were collected, the HDI classification for the year of publication was applied. HDI values are available from 1980, and then from 1990 to present. If a study was conducted prior to 1990, the HDI classification from 1990 was applied. When a country was not included in the HDI ranking, the current country classification from the World Bank was used instead (The World Bank. World Bank country and lending groups. Available from: <https://datahelpdesk.worldbank.org/knowledgebase/articles/906519-world-country-and-lending-groups>).

Category	Inclusion Criteria	Exclusion Criteria
Health status of study participants	<ul style="list-style-type: none"> Studies that enroll participants who are healthy and/or at risk for chronic disease, including those with obesity Studies that enroll some children diagnosed with a disease or with the health outcome of interest: <ul style="list-style-type: none"> Food allergies Atopic dermatitis Allergic rhinitis Asthma 	<ul style="list-style-type: none"> Studies that exclusively enroll mothers who gave birth to preterm (<37 weeks and 0/7 days) infants Studies that exclusively enroll mothers diagnosed with a chronic disease, including severe undernutrition or hospitalized with an illness or injury

LITERATURE SEARCH AND SCREENING RESULTS

The flow chart (**Figure 2**) below illustrates the literature search and screening results for articles examining the systematic review question. The results of the electronic database searches, after removal of duplicates, were screened independently by two NESR analysts using a step-wise process by reviewing titles, abstracts, and full-texts to determine which articles met the inclusion criteria. Refer to **Table 10** for the rationale for exclusion for each excluded full-text article. A manual search was done to find articles that were not identified when searching the electronic databases; all manually identified articles are also screened to determine whether they meet criteria for inclusion.

Figure 2: Flow chart of literature search and screening results

Excluded articles

The table below lists the articles excluded after full-text screening, and includes columns for the categories of inclusion and exclusion criteria (see **Table 9**) that studies were excluded based on. At least one reason for exclusion is provided for each article, though this may not reflect all possible reasons for exclusion. Information about articles excluded after title and abstract screening is available upon request.

Table 10. Articles excluded after full text screening with rationale for exclusion
